6 **Recommendations to assure the quality, safety and efficacy of typhoid**
7 **conjugate vaccines**

8
9 **Replacement of Annex 3 of WHO Technical Report Series, No. 987**

10
11 NOTE:

12
13 This draft document has been prepared for the purpose of inviting comments and suggestions
14 on the proposals contained therein, which will then be considered by the Expert Committee
15 on Biological Standardization (ECBS). The distribution of this document is intended to
16 provide information on the proposed WHO Recommendations to assure the quality, safety
17 and efficacy of typhoid conjugate vaccines (Replacement of Annex 3 of WHO Technical
18 Report Series, No. 987) to a broad audience and to ensure the transparency of the
19 consultation process.

20
21 **The text in its present form does not necessarily represent the agreed formulation of the**
22 **ECBS. Written comments proposing modifications to this text MUST be received by**
23 **18 September, 2020 using the Comment Form available separately** and should be
24 addressed to the Department of Health Products Policy and Standards, World Health
25 Organization, 20 Avenue Appia, 1211 Geneva 27, Switzerland.

26
27 Comments may also be submitted electronically to the Responsible Officer:
28 Dr Richard Isbruckerr at: isbruckerr@who.int.

29
30 The outcome of the deliberations of the ECBS will be published in the WHO Technical
31 Report Series. The final agreed formulation of the document will be edited to be in
32 conformity with the second edition of the *WHO style guide* (KMS/WHP/13.1).

1 Recommendations published by the World Health Organization (WHO) are intended to be
2 scientific and advisory in nature. Each of the following sections constitutes recommendations
3 for national regulatory authorities (NRAs) and for manufacturers of biological products. If an
4 NRA so desires, these WHO Recommendations may be adopted as definitive national
5 requirements, or modifications may be justified and made by the NRA. It is recommended
6 that modifications to these WHO Recommendations are made only on condition that such
7 modifications ensure that the product is at least as safe and efficacious as that prepared in
8 accordance with the recommendations set out below.

10

1 **Abbreviations**

2		
3		
4	ADH	Adipic acid dihydrazide
5	<i>C. freundii</i> s.l.	<i>Citrobacter freundii</i> sensu lato
6	CI	confidence interval
7	CRM ₁₉₇	cross-reactive material 197
8	CTAB	hexadecyltrimethylammonium bromide
9	DT	diphtheria toxoid
10	EDC	1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (also abbreviated EDAC)
11	ELISA	enzyme-linked immunosorbent assay
12	HPAEC-CD	high-performance anion exchange chromatography with conductivity
13		detection
14	HPAEC-PAD	high-performance anion exchange chromatography with pulsed
15		amperometric detection
16	HPLC	high-performance liquid chromatography
17	HPSEC	high-performance size-exclusion chromatography
18	IgA	immunoglobulin A
19	IgG	immunoglobulin G
20	IU	International Unit
21	K _D	(distribution constant)
22	LAL	<i>Limulus</i> amoebocyte lysate (test)
23	LPS	lipopolysaccharide
24	MAT	monocyte activation test
25	MW	molecular weight
26	NMR	nuclear magnetic resonance
27	NRA	national regulatory authority
28	qNMR	quantitative nuclear magnetic resonance
29	SAGE	WHO Strategic Advisory Group of Experts
30	SDS-PAGE	sodium dodecyl sulfate-polyacrylamide gel electrophoresis
31	<i>S. Typhi</i>	<i>Salmonella enterica</i> serovar Typhi
32	TCV	typhoid conjugate vaccine
33	TT	tetanus toxoid
34	Vi-rEPA	Vi polysaccharide conjugated to recombinant exoprotein A of <i>Pseudomonas</i>
35		<i>aeruginosa</i>

1 Introduction

2
3 The WHO Guidelines on the quality, safety and efficacy of typhoid conjugate vaccines were
4 developed following a series of international consultations in 2012 and 2013, and were
5 adopted by the WHO Expert Committee on Biological Standardization at its sixty-fourth
6 meeting in October 2013 (1). Since that time, there have been several major developments
7 with respect to typhoid conjugate vaccines (TCVs), including:

- 8
- 9 ▪ The establishment of WHO international standards for Vi antigens and Vi antibodies
- 10 (human).
- 11 ▪ The licensing of TCVs in some countries.
- 12 ▪ The publication of a WHO Strategic Advisory Group of Experts (SAGE) position
- 13 paper in 2018 recommending the use of TCVs from 6 months to 45 years of age, and
- 14 that the introduction of TCVs into routine immunization programmes be prioritized
- 15 in countries with the highest burden of typhoid disease or with a high burden of
- 16 antimicrobial-resistant *Salmonella* Typhi.
- 17 ▪ Approval of funding support by Gavi, the Vaccine Alliance, for the introduction of
- 18 TCVs in Gavi-eligible countries starting in 2019.
- 19 ▪ WHO Prequalification in 2017 of the Typbar-TCV¹ produced by a manufacturer in
- 20 India.

21
22 The impact of these developments on the production and quality control of TCVs and on their
23 nonclinical and clinical evaluation is reflected in the present revision. As TCVs have been
24 licensed since the development of the original WHO Guidelines in 2013, the current
25 document provides recommendations for the evaluation of such vaccines rather than guiding
26 principles. As a consequence of the increasing demand for TCVs, together with the above-
27 mentioned Gavi decision on funding, new vaccine developers and manufacturers are entering
28 the field and should benefit from updated WHO recommendations. Further clinical evaluation
29 of TCVs, the detailed investigation of immune responses to these vaccines and the search for
30 a true immunological correlate or surrogate of protection are ongoing and Part C of this
31 document may therefore require further updating as new data become available.

32
33 Other significant changes reflected in the current document include the updating in 2017 of
34 the WHO Guidelines on clinical evaluation of vaccines: regulatory expectations (2) which
35 provide methodological considerations for the clinical evaluation of vaccine immunogenicity,
36 efficacy and safety. Manufacturers and regulators should also take note of the decision of the
37 Committee in 2018 to discontinue the inclusion of the general safety (innocuity) test in
38 routine lot release testing requirements for all vaccines in WHO Recommendations,
39 Guidelines and other guidance documents for biological products (3). This test is therefore

¹ See: WHO Prequalified Vaccines at: https://extranet.who.int/gavi/PQ_Web/

1 not included in the manufacturing recommendations provided in Part A of the current
2 document.

3 4 **Terminology**

5
6 The definitions given below apply to the terms as used in these WHO Recommendations.
7 These terms may have different meanings in other contexts.

8
9 **Activated carrier protein:** a carrier protein that has been chemically or physically
10 modified and prepared for conjugation to the polysaccharide.

11 **Activated polysaccharide:** purified polysaccharide that has been modified by a
12 chemical reaction or a physical process in preparation for conjugation to the activated carrier
13 protein.

14 **Carrier protein:** the protein to which the Vi polysaccharide is covalently linked for
15 the purpose of eliciting a T-cell-dependent immune response to the Vi polysaccharide.

16 **Final bulk:** the homogeneous preparation from one or more lots of **purified bulk**
17 **conjugate** in a single container from which the final containers are filled, either directly or
18 through one or more intermediate containers.

19 **Final lot:** a number of sealed, final containers that are equivalent with respect to the
20 risk of contamination that may have occurred during filling and, when it is performed, freeze-
21 drying. A final lot must therefore have been filled from a single container and if freeze-dried,
22 this should be completed in one continuous working session.

23 **Master seed lot:** bacterial suspensions for the production of Vi polysaccharide or the
24 carrier protein should be derived from a strain that has been processed as a single lot and is of
25 uniform composition. The master seed lot is used to prepare the **working seed lots**. Master
26 seed lots should be maintained in the freeze-dried form or be frozen at or below $-45\text{ }^{\circ}\text{C}$.

27 **Purified bulk conjugate:** a purified bulk conjugate is prepared by the covalent
28 bonding of activated Vi polysaccharide to the carrier protein, followed by the removal of
29 residual reagents and reaction by-products. This is the parent material from which the **final**
30 **bulk** is prepared.

31 **Purified polysaccharide:** the material obtained after final purification of
32 polysaccharide. The lot of purified polysaccharide may be derived from a **single harvest** or a
33 pool of single harvests that have been processed together.

34 **Single harvest:** the material obtained from one batch of culture that has been
35 inoculated with the **working seed lot** (or with the inoculum derived from it), harvested and
36 processed during one production run.

37 **Working seed lot:** a quantity of bacterial suspension for the production of Vi
38 polysaccharide or the carrier protein that is of uniform composition and that has been derived
39 from the **master seed lot** by growing the organisms and maintaining them in freeze-dried
40 aliquots or frozen at or below $-45\text{ }^{\circ}\text{C}$. The working seed lot is used to inoculate the
41 production medium.

42

43

1 General considerations

2
3 Typhoid fever is an acute generalized infection of the mononuclear phagocyte system
4 (previously known as the reticuloendothelial system), intestinal lymphoid tissue and gall
5 bladder caused by *Salmonella enterica* serovar Typhi (*S. Typhi*). Paratyphoid fever is a
6 clinically indistinguishable illness caused by *S. enterica* serovar Paratyphi A or B (or, more
7 rarely, C) (4–6). Typhoid and paratyphoid fevers are referred to collectively as enteric fever.
8 In most endemic areas, typhoid accounts for approximately 75–80% of cases of enteric fever.
9 However, in some regions, particularly in some parts of Asia, *S. Paratyphi A* accounts for a
10 relatively larger proportion of all enteric fevers (7–9). Prospective vaccines against *S.*
11 *Paratyphi* are not included in the scope of the current document.

13 Pathogen

14
15 *S. Typhi* is a member of the family *Enterobacteriaceae*. It is a Gram-negative, non-lactose
16 fermenting bacillus that produces trace amounts of hydrogen sulfide. Its antigens include an
17 immunodominant lipopolysaccharide (LPS) O9, flagellar H phase 1 antigen “d” and capsular
18 polysaccharide Vi.

19
20 Vi acts as a virulence factor by preventing anti-O antibody from binding to the O antigen (10)
21 and inhibits the C3 component of the complement system from fixing to the surface of *S.*
22 *Typhi* (11). The Vi antigen is not unique to *S. Typhi* – it is also expressed by *S. Paratyphi C*,
23 *Citrobacter freundii* sensu lato (*C. freundii* s.l.) and some clades of *S. enterica* serovar
24 Dublin. The genes responsible for the biosynthesis of Vi polysaccharide are located in a locus
25 (*viaB*) within the Salmonella pathogenicity island 7 (SPI-7) in the *S. Typhi* chromosome.
26 Several other loci participate in the complex regulation of Vi expression. Almost all *S. Typhi*
27 isolates from blood cultures express Vi. Nevertheless, Vi-negative strains have been
28 identified occasionally, both in sporadic cases as well as during outbreaks (12). Some of these
29 strains are regulatory mutants that can revert to a Vi-positive state (13). However, some Vi-
30 negative isolates from blood have been shown to harbour deletion mutations in critical genes
31 (for example, *tviB*) within the *viaB* locus that render the strains unable to synthesize Vi. This
32 raises the theoretical concern that large-scale usage of Vi-containing vaccines (either
33 polysaccharide or conjugate) could lead to selective pressure that creates a biological
34 advantage for the emergence of Vi-negative strains (14).

36 Pathogenesis

37
38 Typhoid infection begins with ingestion of *S. Typhi* in contaminated food or water. In the
39 small intestine, the bacteria penetrate the mucosal layer and ultimately reach the lamina
40 propria. Translocation from the intestinal lumen mainly occurs through *S. Typhi* targeting M
41 cells overlying gut-associated lymphoid tissue. Within this lymphoid tissue and in the lamina
42 propria, *S. Typhi* invokes an influx of macrophages and dendritic cells that ingest the bacteria
43 but fail to destroy them. Thus, some bacteria remain within macrophages in the lymphoid

1 tissue of the small intestine and flow into the mesenteric lymph nodes where there is an
2 inflammatory response mediated by the release of various cytokines. Bacteria enter the
3 bloodstream via lymphatic drainage, thereby seeding organs of the mononuclear phagocyte
4 system (such as the spleen, liver and bone marrow) and gall bladder by means of a silent
5 primary bacteraemia. After a typical incubation period of 8–14 days the clinical illness
6 begins, usually with the onset of fever, abdominal discomfort and headache. An
7 accompanying low-level secondary bacteraemia occurs.

8
9 Before the availability of fluoroquinolone antibiotics, clinical relapses were observed in 5–
10 30% of patients treated with antibacterial agents such as chloramphenicol and
11 sulfamethoxazole/trimethoprim. These post-treatment relapses occurred when typhoid bacilli
12 re-emerged from their protected intracellular niches within the macrophages of the
13 mononuclear phagocyte system, where the antibacterial agents could not penetrate.

14
15 Several lines of investigation indicate that in a small proportion of patients infected with *S.*
16 *Typhi* who may have premorbid abnormalities of the gall bladder mucosa (such as occurs
17 consequent to gallstones) gall bladder infection becomes chronic (that is, excretion lasts for
18 longer than 12 months) (15). Such chronic carriers, who are themselves not clinically affected
19 by the presence of typhoid bacilli in their system, may excrete the pathogen in their faeces for
20 decades (16). They are thought to serve as a long-term epidemiological reservoir in the
21 community, and to foster the transmission of typhoid wherever there is inadequate sanitation,
22 untreated water supplies and/or improper food handling.

23 24 Epidemiology

25
26 Typhoid fever is restricted to human hosts and in the late nineteenth and early twentieth
27 century was endemic in virtually all countries in Europe and the Americas. Subsequently, the
28 widespread use of chlorination, sand filtration and other means of water treatment drastically
29 reduced the incidence of typhoid fever despite the high prevalence of chronic carriers (15).
30 Typhoid remains endemic in most developing countries and is an important public health
31 problem mainly because large segments of the population lack access to safe water and basic
32 sanitation services (17). In addition, there are limited programmes for detecting carriers and
33 restricting them from handling food.

34 35 Disease burden

36
37 Varied estimates of the annual epidemiological burden (incidence and total number of cases)
38 of typhoid fever have been published in the scientific literature based on the extrapolation of
39 data from various sources. The true incidence of typhoid fever in most regions of developing
40 countries is not known. One study published in 2004 estimated that ~22 million cases occur
41 each year causing 216 000 deaths, predominantly in school-age children and young adults;
42 annual incidence was estimated to be 10–100 per 100 000 population (18). A systematic
43 review of population-based studies published between 1984 and 2005 indicated an annual

1 incidence of 13–976 per 100 000 population each year based on diagnosis by blood culture
2 (19).

3
4 More recent analysis has shown that typhoid fever remains a major cause of enteric disease of
5 children in low- and middle-income countries, with global estimates of disease burden
6 ranging from 11 to 21 million typhoid fever cases and approximately 145 000 to 161 000
7 deaths annually (20). The majority of cases occur in Asia and sub-Saharan Africa but many
8 of the island nations of Oceania also experience a moderate to high incidence of typhoid
9 fever and large outbreaks (21).

10
11 Several factors affect the calculation of the burden of typhoid disease, with one of the most
12 critical being how to confirm that a patient with acute febrile illness has typhoid fever.
13 Unfortunately, there is no rapid, affordable and accurate point-of-care or laboratory
14 diagnostic test to confirm a case of acute typhoid fever. Bone marrow culture is widely
15 recognized as the gold standard but is impractical for widespread use. Blood culture is the
16 most practical accurate confirmatory test but its use alone identifies only 40–80% of the cases
17 that are detectable using bone marrow culture (22–24). Cultures of bile containing duodenal
18 fluid and of skin snips of rose spots can be positive when blood cultures are negative (19).
19 Prior patient treatment with antibacterial agents and the volume of blood cultured also affect
20 the yield of cultures. Reliance on clinical diagnosis alone is not advisable because several
21 other febrile syndromes caused by other microorganisms, such as malaria, dengue, brucellosis
22 and leptospirosis, can be confused with typhoid in both adults and children.

23
24 The incidence of typhoid, its age-specific distribution and the severity of clinical disease
25 gleaned from passive surveillance implemented at health facilities often appear quite different
26 to data acquired through active surveillance. During active surveillance, households are
27 visited systematically once or twice weekly to detect fever among their members, and mild or
28 early clinical illness can be detected. A 2008 study reported on the incidence of typhoid fever
29 detected through passive surveillance (and through modified passive surveillance in two
30 countries where additional health clinics were introduced into the community) in five Asian
31 countries (25). The incidence of typhoid fever ranged from 15.3 per 100 000 person-years
32 among people aged 5–60 years in China to 451.7 per 100 000 person-years among children
33 aged 2–15 years in Pakistan (25). More recently, the estimated incidence in Nepal ranged
34 from 297 to 449 per 100 000 person-years, with greater incidence occurring during the
35 summer months (26). Incidence data from the placebo control groups in vaccine trials also
36 provide information on the incidence of typhoid fever in multiple geographical areas and
37 locations. However, because vaccine efficacy trials are typically carried out in areas with
38 high endemicity, caution must be exercised when extrapolating these incidence rates to other
39 populations. New data on age-specific occurrence in certain geographical regions, as in some
40 sites in South Asia, confirm that typhoid fever of sufficient severity to seek medical care is
41 common in the 1–4 year-old age group, with a large proportion of disease occurring in
42 children between 6 months and 2 years of age (17).

43

1 There has also been an increasing number of major outbreaks associated with antimicrobial-
2 resistant *S. Typhi* (17, 27–31), with the increased occurrence of outbreaks due to multidrug-
3 resistant typhoidal *Salmonella* serovars being of particular concern. Extensively drug-
4 resistant variants of *S. Typhi* have also emerged in India, Bangladesh and Pakistan that
5 severely limit treatment options and are therefore becoming increasingly difficult to treat (32,
6 33). The *S. Typhi* H58 clade, with IncHI1 plasmids that carry multidrug-resistance genes and
7 target site mutations mediating fluoroquinolone resistance, is responsible for much of the
8 recent and dramatic spread of resistant strains in countries, such as occurred in Pakistan in
9 2018 (33, 34). This clade is believed to have emerged on the Indian subcontinent about 30
10 years ago and then spread to South-East Asia and more recently to sub-Saharan Africa (33).
11 The emergence of extensively antibiotic-resistant *S. Typhi* (resistant to first- and second-line
12 antibiotics) and the implications of this for disease control were reviewed in 2017 (20). The
13 global pattern of drug-resistant *S. Typhi* is dynamic and changing in each location and over
14 time. For example, in Ho Chi Minh City, Viet Nam the proportion of strains with a
15 diminished susceptibility to fluoroquinolones increased from less than 5% to 80% within a
16 few months in 1998 (35). A large-scale outbreak of extensively drug-resistant typhoid in
17 Pakistan further demonstrates the importance of understanding local resistance patterns to
18 enable the selection of appropriate antibiotics for the management of typhoid fever cases
19 (33).

20
21 Prior to the availability of antibacterial agents, typhoid resulted in a case-fatality rate of
22 approximately 10–20% (36). Current estimates covering the post-antibiotic era range from
23 1% to 4% of those who receive adequate therapy (37). Most of the mortality occurs in
24 developing countries, predominantly in Asia. A 2008 review (19) reported community-based
25 mortality ranging from 0% to 1.8% across five studies in developing countries; hospital-
26 based mortality ranged from 0% to 13.9% across all ages in 12 studies; and in children
27 younger than 15 years, mortality ranged from 0% to 14.8% across 13 studies. Hospitalization
28 rates of 2–40% have also been reported (25) indicating that the disease can be severe in a
29 considerable proportion of patients. The evolution and spread of multiple antibiotic resistant
30 *S. Typhi* described above further complicates the situation and leads to an increased
31 proportion of patients experiencing clinical treatment failure and complications, increasing
32 hospital admission and prolonged hospital stay (20).

33
34 Few studies have estimated the prevalence of chronic carriers of typhoid and paratyphoid in
35 developing countries. One survey in Santiago, Chile, conducted when typhoid fever was
36 highly endemic there in the 1970s, estimated a crude prevalence of 694 typhoid carriers per
37 100 000 population (38). In Kathmandu, Nepal, among 404 patients (316 females and 88
38 males) with gall bladder disease undergoing cholecystectomy, *S. Typhi* was isolated from
39 3.0% of bile cultures and *S. Paratyphi A* from 2.2% (39). Since the overall prevalence of
40 cholelithiasis in the population of Kathmandu was not known, the overall prevalence of
41 chronic carriage in that population could not be calculated. The role of chronic carriers in the
42 transmission of typhoid fever is still unclear (17) but is thought to vary between settings of
43 high, medium and low disease incidence (18, 40). However, chronic carriers may represent a

1 long-term reservoir of infection and contribute to the persistence of typhoid fever through
2 ongoing shedding of *S. Typhi* and *S. Paratyphi* into the environment, possibly contaminating
3 water supplies.

4 5 Clinical features

6
7 *S. Typhi* infection results in a wide spectrum of clinical features, most often characterized by
8 persisting high-grade fever, abdominal discomfort, malaise and headache. Important clinical
9 signs in hospitalized patients include hepatomegaly (41%), toxicity (33%), splenomegaly
10 (20%), obtundation (2%) and ileus (1%) (41). Before antibacterial agents became available,
11 gross bleeding from the gastrointestinal tract and perforations occurred in 1–3% of untreated
12 patients and hospital-based reports suggest that more than 50% of patients may have serious
13 complications. In one 2005 study (42), numerous extra-intestinal complications were reported
14 on involving the central nervous system (3–55%), the hepatobiliary system (1–26%), the
15 cardiovascular system (1–5%), the pulmonary system (1–6%), bones and joints (less than
16 1%) and the haematological system (rarely). Intestinal perforations leading to peritonitis and
17 death continue to be reported, albeit rarely, in some settings. Interestingly, the emergence of
18 multidrug-resistant strains has been associated not only with failure to respond to antibiotic
19 treatment but also with changes in the severity and clinical profile of enteric fever (5, 43).

20 21 Immune responses to natural infection

22
23 Natural typhoid infection is usually associated with detectable serum antibodies and mucosal
24 secretory immunoglobulin A (IgA) intestinal antibody against various *S. Typhi* antigens.
25 However, cell-mediated immune responses are also measurable (44–48). In areas where
26 typhoid is endemic, there is an age-related increase in the prevalence and geometric mean
27 titre of anti-Vi antibodies (49). Anti-flagella (H antigen) serum IgG antibodies following
28 natural infection are long lived and have been studied for seroepidemiological surveys (50).

29
30 While serological responses to LPS and flagella antigens tend to be quite strong and are
31 commonly found in patients with culture-confirmed acute typhoid fever, only about 20% of
32 such patients exhibit significant levels of anti-Vi antibody (51, 52). In contrast, high
33 concentrations of anti-Vi serum IgG antibody are detected in 80–90% of chronic carriers (51,
34 52).

35
36 Cell-mediated immunity also appears to play a part in protection – it has been observed that
37 peripheral blood mononuclear leukocytes of healthy adults residing in typhoid-endemic areas,
38 and who have no history of typhoid, proliferate upon exposure to *S. Typhi* antigens (53).

39 40 Disease control

41
42 As with other enteric and diarrhoeal diseases, typhoid fever occurs predominantly in
43 populations with inadequate access to safe water and basic sanitation. Effective typhoid

1 control requires a comprehensive approach that combines immediate measures, such as
2 accurate and rapid diagnostic confirmation of infection and timely administration of
3 appropriate antibiotic treatment, with sustainable longer-term solutions such as providing
4 access to safe water and basic sanitation services, health education, appropriate hygiene
5 among food handlers and typhoid vaccination. There is evidence that vaccination against
6 typhoid can substantially reduce typhoid fever burden when targeted towards high-risk age
7 groups and geographical areas, and when combined with improved sanitation (54). The most
8 recent WHO position paper on the use of typhoid vaccines was published in 2018 (17).

10 Typhoid vaccines

12 **Inactivated whole-cell vaccine**

14 Inactivated *S. Typhi* bacteria (heat inactivated and phenol preserved) were first used to
15 prepare parenteral vaccines more than 100 years ago. In the 1960s, WHO sponsored field
16 trials that evaluated the efficacy of inactivated parenteral whole-cell vaccines in several
17 countries (55, 56) and documented a moderate level of efficacy lasting up to 7 years (57).
18 Data from studies of human immune responses and immunogenicity studies in rabbits
19 suggested that anti-H antibodies might represent an immune correlate of protection (58); later
20 extrapolation from the results of mouse protection studies suggested that responses to Vi
21 antigen may also correlate with protection (59, 60). However, these vaccines were associated
22 with considerable rates of systemic adverse reactions (61) and never became widely accepted
23 public health tools, and are thus no longer produced.

25 **Live-attenuated Ty21a oral vaccine**

27 In the early 1970s, an attenuated strain of *S. Typhi* was developed through chemically
28 induced mutagenesis of pathogenic *S. Typhi* strain Ty2 (59). The resultant mutant strain lost
29 the activity of the epimerase enzyme encoded by the *galE* gene and no longer expressed the
30 Vi antigen. The vaccine was found to be stable, safe and efficacious in adults as well as
31 children (62–66). The level of protective immunity achieved varied according to the
32 formulation of the vaccine, the number of doses administered and the interval between doses.
33 For example, three doses of a provisional formulation of vaccine administered to around
34 32 000 children (aged 6–7 years) in Alexandria, Egypt gave a point estimate of efficacy of
35 95% (95% confidence interval (CI) = 77–99%) during 3 years of follow-up (67). Three doses
36 of enteric-coated capsules administered to Chilean schoolchildren (aged 6–19 years) using
37 two different dose intervals (either alternate days or 21 days between doses) gave a point
38 estimate of efficacy of 67% (95% CI = 47–79%) during 3 years of follow-up. For the group
39 receiving doses on alternate days, the point estimate of protection over 7 years was 62%
40 (95% CI = 48–73%) (56, 68). For the group receiving each dose after a 21-day interval, the
41 corresponding point estimate of protection was 49% (95% CI = 24–66%). Another trial
42 among Chilean schoolchildren involved the administration of four doses within 7 days and
43 demonstrated even greater protection (69). Human challenge studies showed that 5–8 doses

1 of Ty21a oral vaccine resulted in high rates of anti-LPS antibody seroconversion and 87%
2 protective efficacy (70). However, more recent human challenge studies showed that a three-
3 dose Ty21a immunization schedule resulted in a protective efficacy of only 35% after
4 challenge when using the end-points of fever and/or bacteraemia as a diagnosis of typhoid
5 (71). When efficacy was recalculated using the same definition for typhoid diagnosis used in
6 the original vaccine/challenge studies (fever with subsequent microbiological confirmation)
7 then Ty21a efficacy reached 80% (71), which is similar to that reported in the older challenge
8 studies.

10 Two field trials in Chile (66) and Indonesia (65) compared the use of enteric-coated capsules
11 with three doses of the liquid formulation. In both trials, the liquid formulation was
12 associated with greater efficacy than the capsules. In Chile, where the doses were given on
13 alternate days, the results for the liquid formulation were superior to those obtained in
14 Indonesia, where the doses were administered 1 week apart (point estimate of efficacy = 77%
15 in Chile and 53% in Indonesia). In Chile, 78% protection was documented up to 5 years
16 following vaccination with the liquid formulation (68). However, the previously marketed
17 liquid formulation is no longer produced, and only enteric-coated capsules are currently
18 available (17).

20 All countries in which Ty21a is licensed utilize a three-dose course of enteric-coated capsules
21 taken on alternate days, with the exception of the United States of America (USA) and
22 Canada, which both use a four-dose course. This vaccine was first licensed in Europe in 1983
23 and in the USA in 1989, and is approved for use in individuals older than 6 years. Because
24 the vaccine is highly acid labile, stomach acidity must be neutralized or bypassed when
25 Ty21a is fed orally. There is indirect evidence that large-scale vaccination with Ty21a may
26 provide some degree of protection against typhoid to people who have not been vaccinated
27 through the mechanism of herd protection.

29 **Vi polysaccharide vaccine (unconjugated)**

31 Technological advances in the late 1960s made it possible to purify Vi polysaccharide
32 without damaging its antigenic properties and to prepare vaccines that are almost totally free
33 of contaminating LPS (72); these vaccines are associated with low rates of febrile reactions
34 (1–2%). Vi polysaccharide vaccine was first licensed in the USA in 1994 and since then
35 several products have been licensed for use in individuals aged 2 years and older. One such
36 product (Typhim-Vi) has been prequalified by WHO.¹

38 The immunological basis of protection by purified Vi polysaccharide parenteral vaccines is
39 the generation of serum anti-Vi IgG antibodies in 85–90% of vaccine recipients older than 2
40 years.

¹ See: WHO Prequalified Vaccines at: https://extranet.who.int/gavi/PQ_Web/

1 Clinical trials with these vaccines showed a rise in anti-Vi antibody titres in adults and
2 children (73–75). However, subsequent inoculations with Vi did not boost the antibody
3 response. Although a single dose has been associated with the persistence of antibodies for up
4 to 3 years in some recipients, many adult recipients in non-endemic areas showed a marked
5 drop in antibody levels after 2 years (76, 77). An epidemic of typhoid fever among French
6 soldiers deployed in Côte d’Ivoire showed that the risk of typhoid fever was significantly
7 higher in persons vaccinated more than 3 years previously (78).

8
9 Field trials in children and adults in Nepal given a single 25 µg dose showed 72% vaccine
10 efficacy during 17 months of follow-up (73) and a field trial in schoolchildren in South
11 Africa (also using a single 25 µg dose) showed 60% protection during 21 months of follow-
12 up (74). In South Africa, protection was found to decline to 55% at 3 years (79). Another
13 field trial in China in people aged 3–50 years given a single 30 µg dose showed 69% efficacy
14 during 19 months of follow-up (80). Thus, while a single dose of an unconjugated Vi
15 polysaccharide vaccine provides moderate protection, the available data suggest that
16 protective efficacy does not last beyond 3 years and revaccination is necessary within that
17 time.

18
19 Most data suggest that children younger than 5 years respond poorly to unconjugated Vi
20 polysaccharide vaccines (81). However, one cluster-randomized trial in Kolkata, India (82)
21 found that protective efficacy among young children (aged 2–4 years) was 80%, which was
22 higher than that observed in children aged 5–14 years (56%) and in older persons (46%). In
23 contrast, a cluster-randomized field trial of similar design and using the same Vi
24 polysaccharide vaccine in Karachi, Pakistan reported an adjusted total protective
25 effectiveness of –38% (95% CI = minus 192–35%) for children aged 2–5 years compared
26 with 57% (95% CI = 6–81%) for children aged 5–16 years (81).

27
28 Thus, a single dose of unconjugated Vi polysaccharide vaccine can provide moderate
29 protection for a limited duration, but such vaccines have the usual limitations associated with
30 polysaccharide vaccines, including poor immunogenicity in infants and young children,
31 short-lived immunity and lack of anamnestic immune responses to subsequent doses (76, 82,
32 83).

34 **Vi polysaccharide–protein conjugate vaccine**

35
36 Experience with other polysaccharide–protein conjugate vaccines (such as *Haemophilus*
37 *influenzae* type b, meningococcal and pneumococcal vaccines) has shown that conjugation to
38 a carrier protein overcomes many of the limitations associated with unconjugated bacterial
39 polysaccharides. On the basis of this, several Vi polysaccharide–protein conjugate vaccines
40 have been developed or are under development. These include vaccines based on Vi
41 polysaccharide conjugated to tetanus toxoid (TT), diphtheria toxoid (DT), the nontoxic
42 mutant of diphtheria toxin cross-reactive material 197 (CRM₁₉₇) as well as on the prototype
43 Vi polysaccharide conjugated to nontoxic recombinant exoprotein A of *Pseudomonas*

1 *aeruginosa* (Vi-rEPA) (84). One TCV that uses Vi prepared from *C. freundii* s.l. and CRM₁₉₇
2 as the carrier protein has been shown to elicit a higher level of anti-Vi IgG compared to an
3 unconjugated Vi polysaccharide vaccine in European adults who have never been exposed to
4 typhoid fever (85). Vi preparations from *C. freundii* s.l. are immunologically
5 indistinguishable from and structurally similar to those from *S. Typhi* (85–87), though size
6 and behaviour differences have been observed for Vi polysaccharide from *S. Typhi* and *C.*
7 *freundii* s.l. using high-performance size-exclusion chromatography (HPSEC) (87).

8
9 Four TCVs have been licensed in India since 2008; three consisting of Vi polysaccharide
10 conjugated to TT and one to CRM₁₉₇. Other TCVs are in late-stage development in some
11 Asian countries. Typbar-TCV (a Vi–TT conjugate vaccine) was licensed in India in 2013 for
12 use in children aged 6 months or older and in adults up to 45 years of age on the basis of
13 immunogenicity and safety demonstrated in a Phase III study in an endemic setting (17, 88).
14 The results showed that anti-Vi antibody titres were significantly higher among recipients of
15 Typbar-TCV than those vaccinated with the unconjugated Vi polysaccharide vaccine.
16 Furthermore, the high geometric mean titres of IgG anti-Vi antibodies elicited by a single
17 dose of Typbar-TCV persisted for up to 5 years in approximately 84% of children. The
18 vaccine was prequalified by WHO in December 2017. A protective efficacy of 87.1% (95%
19 CI = 47.2–96.9%) against persistent fever associated with positive blood culture for *S. Typhi*
20 was subsequently demonstrated in human challenge studies (89). Interim data on the efficacy
21 of Typbar-TCV in an endemic population in Nepal have also recently been published (26).
22 These data, from a Phase III participant-observer blinded randomized study in children aged
23 9 months to 16 years of age, confirmed that a single dose of Typbar-TCV was safe,
24 immunogenic and effective in this field setting, with an efficacy of 81.6% (95% CI = 58.8–
25 91.8%) (26). This conclusion is supported by new data from Pakistan (vaccine efficacy =
26 ~89%) and India (vaccine efficacy = 82%). In view of the improved immunological
27 properties of TCVs compared to the other available typhoid vaccine types, their suitability for
28 use in young children and longer expected duration of protection, the WHO SAGE
29 recommended such vaccines as the preferred type for use in individuals from 6 months to 45
30 years of age, and that the introduction of TCVs be prioritized in countries with the highest
31 burden of typhoid fever or with a high burden of antimicrobial-resistant *S. Typhi* (17).

32
33 Although no internationally agreed correlates or surrogates of protection have yet been
34 identified for Vi conjugate vaccines, a number of suggested correlates have been proposed.
35 Based on the assay used to measure anti-Vi IgG serum antibodies generated in response to
36 the prototype United States National Institutes of Health Vi-rEPA conjugate vaccine in Viet
37 Nam, a threshold value of 4.3 µg/mL anti-Vi antibody measured by enzyme-linked
38 immunosorbent assay (ELISA) was found to be associated with a high level of sustained
39 protection lasting 4 years after vaccination (90, 91). A placebo-controlled randomized
40 double-blind study in Vietnamese children aged 2–5 years in a highly endemic area produced
41 an estimated efficacy of 89% for the Vi-rEPA vaccine over 46 months of follow-up (92, 93).
42 However, although a study to evaluate Vi-TT in Nepal (94) found that higher anti-Vi IgG
43 levels are associated with greater protection against typhoid infection, no threshold level

1 could be identified at which the probability of infection becomes negligible within the range
2 of antibody levels induced by vaccination.

3
4 It is acknowledged that there are difficulties in comparing any immunogenicity data
5 generated using new TCVs and current ELISA protocols to the data generated in the original
6 Vi-rEPA trial in Viet Nam (20). However, the inclusion of a working reference serum
7 calibrated against the First WHO International Standard for anti-typhoid capsular Vi
8 polysaccharide immunoglobulin G (see **International reference materials** below) can
9 improve the interpretation of data from clinical trials (95, 96). The use of this WHO
10 international standard will ensure consistency in determining serum titres and thus allow for
11 the comparison of data generated by different assays and/or different laboratories.

12
13 It has been suggested that variability in the biophysical properties of antibodies induced by Vi
14 polysaccharide and Vi-TT conjugated vaccines (such as antibody subclass distribution and
15 avidity) may also impact protective outcomes. One recent study (97) identified serum Vi IgA
16 as a biomarker of protective immunity against typhoid fever and quantified the concentration
17 of Vi IgA in vaccine recipients. However, no correlate of protection was identified and it was
18 concluded that further work was needed to determine whether IgA represents a true correlate
19 of protection or a surrogate marker of another underlying immune response.

20 21 Challenge studies

22
23 The development of vaccines against typhoid fever has been complicated by the human host
24 restriction of *S. Typhi*, the lack of clear correlates of protection, the required scale of field
25 trials of efficacy and uncertainty about the estimation of vaccine impact. Historically, only
26 the chimpanzee model of the 1960s demonstrated a pathogenesis and clinical illness that
27 somewhat recapitulated typhoid fever in humans (98–101). However, the chimpanzee model
28 is no longer permissible and recent animal models (including ones based on “humanized”
29 small animals) have not been able to mimic the disease process of human typhoid, despite
30 many attempts (102–107). Instead, a human challenge model has been used to overcome
31 some of these difficulties and to provide direct estimation of efficacy in vaccine recipients
32 who are deliberately challenged with the pathogen in a controlled setting (108, 109). The first
33 setting during the 1950s to early 1970s involved volunteers in a penal institution (70, 110–
34 112) whereas more recent studies have involved community volunteers (108, 109).

35 36 International reference materials

37
38 Two WHO international standards for Vi polysaccharide have been developed to measure the
39 polysaccharide content of typhoid vaccines (113–115). The Vi polysaccharide content of
40 these two standards was assessed using quantitative nuclear magnetic resonance (qNMR).
41 The First WHO International Standard for *Salmonella* Typhi Vi polysaccharide (NIBSC code
42 16/126) has a content of 2.03 ± 0.10 mg Vi polysaccharide/ampoule. The First WHO
43 International Standard for *Citrobacter freundii* Vi polysaccharide (NIBSC code 12/244) has a

1 content of 1.94 ± 0.12 mg Vi polysaccharide/ampoule (113–115). Both standards can be used
2 in physicochemical assays, for example, high-performance anion exchange chromatography
3 with pulsed amperometric detection (HPAEC-PAD) or in immunoassays such as rocket
4 immunoelectrophoresis to measure the amount of Vi polysaccharide in final product, bulk
5 conjugate and process intermediates. In addition, these Vi polysaccharide standards can be
6 used as coating antigens for in-house ELISAs (115–117). When analyzing the content of Vi
7 polysaccharide vaccines the homologous Vi polysaccharide standard should be used. For
8 example, if the conjugate has been made with *Citrobacter* Vi polysaccharide then the
9 *Citrobacter* Vi polysaccharide standard would be the more appropriate standard to use. The
10 use of these WHO standards decreases the variability of in-house assays (114, 115).

11
12 In addition, a First WHO International Standard for anti-typhoid capsular Vi polysaccharide
13 IgG (human) (NIBSC code 16/138) is available and consists of pooled post-immunization
14 sera obtained following vaccination with plain Vi polysaccharide or conjugated Vi
15 polysaccharide according to the immunization schedule of Jin et al. (89). This international
16 standard was evaluated in both commercial and in-house ELISAs, and assigned a
17 concentration of 100 International Units (IU)/ampoule (95, 116, 117). This primary reference
18 standard should be used as a calibrant for in-house and working standards that are used to
19 evaluate the immunogenicity of licensed vaccines and vaccine candidates in clinical studies
20 (116, 117). The United States reference reagent Vi-IgG_{R1,2011} was also included in the
21 collaborative study to establish the standard material 16/138 and was determined to contain
22 163 IU/mL (116). As Vi-IgG_{R1,2011} had been established as containing 33 µg anti-Vi IgG/mL
23 (90) (equivalent to 33 µg/vial) it can be assumed that 1 µg anti-Vi IgG/mL is equivalent to
24 4.94 IU/mL.

25
26 A further collaborative study was then conducted in which the standard materials 16/138 and
27 12/244 were used to evaluate a standardized in-house ELISA based on a co-coating of Vi
28 polysaccharide and poly-L-lysine. The results obtained indicate that this generic assay would
29 be a suitable alternative to the commercial Vi polysaccharide ELISA (96).

30
31 All of the above WHO international standards are available from the National Institute for
32 Biological Standards and Control, Potters Bar, the United Kingdom.¹ For the latest list of
33 appropriate WHO international standards and reference materials, the WHO Catalogue of
34 International Reference Preparations should be consulted.²

¹ See: www.nibsc.org/products

² See: www.who.int/bloodproducts/catalogue

1 **Part A. Manufacturing recommendations**

3 **A.1 Definitions**

5 **A.1.1 International name and proper name**

7 The international name of the vaccine should be “typhoid conjugate vaccine”. The proper
8 name should be the equivalent of the international name in the language of the country of
9 origin.

11 The use of the international name should be limited to vaccines that meet the specifications
12 given below.

14 **A.1.2 Descriptive definition**

16 A typhoid conjugate vaccine (TCV) is a preparation of *S. Typhi* or *C. freundii* s.l. Vi
17 polysaccharide covalently linked to a carrier protein. It may be formulated with a suitable
18 adjuvant and/or a preservative. It should be presented as a sterile aqueous suspension or as
19 freeze-dried material. The preparation should meet all of the specifications given below.

21 **A.2 General manufacturing recommendations**

23 The general guidance provided in WHO good manufacturing practices for pharmaceutical
24 products: main principles (118) and WHO good manufacturing practices for biological
25 products (119) should be followed at establishments manufacturing Vi conjugate vaccines.

27 The production method should be shown to consistently yield Vi conjugate vaccines of
28 satisfactory quality as outlined in these WHO Recommendations. All assay procedures used
29 for quality control of the conjugate vaccine and vaccine intermediates should be validated.
30 Post-licensure changes to the manufacturing process and quality control methods should also
31 be validated and may require approval from the NRA prior to implementation (120–122).

33 Production strains for Vi polysaccharide and the carrier proteins may represent a hazard to
34 human health and should be handled under appropriate containment conditions based on risk
35 assessment and applicable national and local regulations (123). Standard operating
36 procedures should be developed to deal with emergencies arising from accidental spills, leaks
37 or other accidents. Personnel employed by the production and control facilities should be
38 adequately trained. Appropriate protective measures, including vaccination, should be
39 implemented if available.

41 If raw materials used in the culture media or in subsequent manufacturing steps contain
42 materials of animal origin, they should comply with the current *WHO Guidelines on*

1 *transmissible spongiform encephalopathies in relation to biological and pharmaceutical*
2 *products (124).*

4 A.3 Control of source materials

6 A.3.1 Bacterial strains

8 The bacterial strain used for preparing Vi polysaccharide or carrier protein should be from a
9 single well-characterized stock that can be identified by a record of its history, including the
10 source from which it was obtained, number of passages and the tests used to determine the
11 characteristics of the strain. Information regarding materials of animal origin used during
12 passages of the bacterial strain should be provided, such as compliance with the current *WHO*
13 *Guidelines on transmissible spongiform encephalopathies in relation to biological and*
14 *pharmaceutical products (124)* or a statement of risk assessment.

16 A.3.1.1 Bacterial strain for preparing Vi polysaccharide

18 The strain used should be capable of stably producing Vi polysaccharide. *S. Typhi* and *C.*
19 *freundii* s.l. have been shown to be suitable sources of Vi polysaccharide. Proton nuclear
20 magnetic resonance (¹H NMR) spectroscopy, immunochemical tests or any other suitable
21 method may be used for confirming the identity of the polysaccharide.

23 A.3.2 Bacterial seed lot system

25 The production of both Vi polysaccharide and the carrier protein should be based on a seed
26 lot system consisting of a master seed and a working seed. Cultures derived from the working
27 seed should have the same characteristics as the cultures of the strain from which the master
28 seed lot was derived. Each new seed lot prepared should be characterized using appropriate
29 control tests to ensure comparable quality attributes to those of the previous seed lot. New
30 seed lots should also be shown to have comparable Vi polysaccharide or carrier protein yields
31 in routine manufacturing prior to their use.

33 The control tests for master and working seed lots may include culture purity, strain identity,
34 Vi polysaccharide immunoassay or any other method(s) suitable for the characterization of Vi
35 polysaccharide or carrier protein.

37 A.3.3 Bacterial culture media

39 Manufacturers are encouraged to avoid the use of materials of animal origin. However, if the
40 culture medium does contain materials of animal origin, these should comply with the current
41 *WHO Guidelines on transmissible spongiform encephalopathies in relation to biological and*
42 *pharmaceutical products (124)*. The use of materials of animal origin should be discussed
43 with and approved by the NRA.

1

2 The culture medium used to prepare bacterial seed lots and commercial vaccine lots should
3 also be free from substances likely to cause toxic or allergic reactions in humans.

4 Additionally, the liquid culture medium used to produce polysaccharide intermediate should
5 be free from ingredients that will form a precipitate upon addition of chemical compounds,
6 such as hexadecyltrimethylammonium bromide (CTAB), used for the purification of the Vi
7 polysaccharide.

8

9 A.4 Control of vaccine production

10

11 **A.4.1 Control of polysaccharide antigen production**

12

13 The Vi polysaccharides that are used in licensed vaccines are defined chemical substances if
14 they are prepared to similar specifications, for example as described in the WHO
15 Requirements for Vi polysaccharide typhoid vaccine (125) and the requirements set out in the
16 following sections of the current document. As a result, it is expected that they will be
17 suitable for the preparation of TCVs.

18

19 ***A.4.1.1 Single harvests for preparing Vi polysaccharide antigen***

20

21 The consistency of the production process should be demonstrated by monitoring the growth
22 of the organisms and the yield of Vi polysaccharide.

23

24 ***A.4.1.1.1 Consistency of microbial growth for antigen production***

25

26 The consistency of the growth of production strains should be demonstrated by monitoring
27 the growth rate, pH, pO₂ and the final yield of Vi polysaccharide – though monitoring should
28 not be limited to these parameters.

29

30 ***A.4.1.1.2 Bacterial purity***

31

32 Samples of the culture should be taken before inactivation and examined for microbial
33 contamination. The purity of the culture should be verified using suitable methods, such as
34 inoculation on appropriate culture media. If contamination is found, the culture and any
35 product derived from it should be discarded.

36

37 ***A.4.1.2 Bacterial inactivation and antigen purification***

38

39 Generally, *S. Typhi* is inactivated using a suitable method such as chemical treatment (for
40 example, with formaldehyde), heating or other alternative methods prior to purification. The
41 inactivation process should be validated and monitored using a validated test during routine
42 manufacturing. If a chemical agent is used for inactivation, its residual level should be

1 controlled as described in section A.4.1.3.10 below. *C. freundii* s.l. cultures are, generally,
2 not inactivated prior to processing.

3
4 After inactivation where appropriate, the biomass of *S. Typhi* or *C. freundii* s.l. is removed
5 using an appropriate method such as centrifugation or tangential flow filtration. The Vi
6 polysaccharide may be then purified from the supernatant by precipitation with CTAB or by
7 other suitable methods approved by the NRA. Bioburden should be monitored during
8 purification. The purified Vi polysaccharide should be stored under appropriate conditions
9 that have been shown to retain the integrity of the Vi polysaccharide (for example, powder at
10 2–8 °C or lower and solution at –20 °C or lower). Hold times should be based on the results
11 of stability studies and approved by the NRA.

12 13 ***A.4.1.3 Control of purified Vi polysaccharide antigen***

14
15 Each lot of purified Vi polysaccharide should be tested for identity and purity, as well as the
16 additional parameters described below. All tests should be validated and any test limits or
17 ranges not defined by a pharmacopoeia should be agreed with the NRA.

18 19 ***A.4.1.3.1 Identity***

20
21 Vi polysaccharide is a linear homopolymer composed of (1 →4)-2-acetamido-2-deoxy- α -D-
22 galacturonic acid that is *O*-acetylated at carbon-3 (126).

23
24 A test should be performed on the purified polysaccharide to verify its identity, such as NMR
25 spectroscopy (127) or a suitable immunoassay, as appropriate and convenient.

26 27 ***A.4.1.3.2 Molecular size or mass distribution***

28
29 The molecular size or mass distribution of each lot of purified polysaccharide should be
30 estimated to assess the consistency of each batch. The distribution constant (K_D) should be
31 determined by measuring the molecular size distribution of the polysaccharide at the main
32 peak of the elution curve obtained by a suitable chromatographic method. The K_D value or
33 the mass distribution limits, or both, should be established and shown to be consistent from
34 lot to lot for a given product. To ensure consistency and a defined proportion of high
35 molecular size polysaccharide for gel filtration using HPSEC, typically at least 50% of the Vi
36 polysaccharide should elute at a K_D value less than a predefined value, depending on the
37 chromatographic method used. However, if molecular weight (MW) is determined by static
38 light scattering then there is no need for a K_D value since it is a coefficient that is dependent
39 on the column used.

40
41 An acceptable level of consistency should be agreed with the NRA. Alternatively, calculation
42 of the peak width at the 50% level can be used to analyse the distribution of MW. Suitable
43 detectors for this purpose include a refractive index detector (128), alone or in combination

1 with a static light scattering detector (for example, multi-angle laser light scattering detector)
2 (87) and/or a viscometer. The methodology used should be validated to demonstrate
3 sufficient resolution in the appropriate MW range. Manufacturers are encouraged to produce
4 Vi polysaccharide that has a consistent distribution of molecular size.

5
6 Due to its high viscosity on molecular sizing columns, the Vi polysaccharide does not behave
7 the same as other polysaccharides; therefore, column matrices and eluents should be carefully
8 chosen to ensure a representative recovery (87).

10 A.4.1.3.3 Polysaccharide content

11
12 The concentration of the Vi polysaccharide in its *O*-acetylated acid form can be measured
13 using the Hestrin method (114, 129) or the acridine orange method (126, 130). More-specific
14 methods, such as NMR (127) or HPAEC-PAD (130, 131), are also acceptable, and a suitable
15 immunoassay, for example rocket immunoelectrophoresis or ELISA, may be considered. A
16 suitable reference preparation of Vi polysaccharide calibrated against the First WHO
17 International Standard for *Citrobacter freundii* Vi polysaccharide (NIBSC code 12/244) or
18 against the First WHO International Standard for *Salmonella* Typhi Vi polysaccharide
19 (NIBSC code 16/126) should be used where appropriate (see **International reference**
20 **materials** above). These methods should be validated and agreed with the NRA.

22 A.4.1.3.4 *O*-acetyl content

23
24 The *O*-acetyl content of the purified Vi polysaccharide is important for the immunogenicity
25 of Vi (87, 126, 132) and should be at least 2.0 mmol/g polysaccharide (52% *O*-acetylation),
26 unless justified. The Hestrin method (129), NMR (127, 133), high-performance anion
27 exchange chromatography with conductivity detection (HPAEC-CD) (134) or other suitable
28 methods may be used to quantitatively determine *O*-acetylation. The methods and acceptance
29 criteria used should be agreed with the NRA.

31 A.4.1.3.5 Moisture content

32
33 If the purified polysaccharide is to be stored as a dried form, the moisture content should be
34 determined using suitable validated methods, and the results should be within established
35 limits. The methods and acceptable limits used should be agreed with the NRA.

37 A.4.1.3.6 Protein impurity

38
39 The protein content should be determined using a suitable validated method, such as that of
40 Lowry et al. (135), and using bovine serum albumin as a reference. Sufficient polysaccharide
41 should be assayed to accurately detect protein contamination. Each lot of purified
42 polysaccharide should typically contain no more than 1% (weight/weight) of protein.

1 *A.4.1.3.7 Nucleic acid impurity*

2
3 Each lot of purified polysaccharide should contain no more than 2% nucleic acid by weight
4 as determined by ultraviolet spectroscopy on the assumption that the absorbance of a 10 g/L
5 nucleic acid solution contained in a cuvette of 1 cm path length at 260 nm is 200 (136). Other
6 validated methods may be used. Sufficient polysaccharide should be assayed to accurately
7 determine nucleic acid contamination.

8
9 *A.4.1.3.8 Phenol content*

10
11 If phenol has been used to prepare the Vi polysaccharide antigen, each lot should be tested
12 for phenol content using a validated method approved by the NRA. The phenol content
13 should be expressed in µg/mg of purified Vi antigen and shown to be consistent and within
14 the limits approved by the NRA.

15
16 *A.4.1.3.9 Endotoxin*

17
18 The endotoxin content of each lot of purified Vi polysaccharide should be determined and
19 shown to be within limits agreed with the NRA. Suitable in vitro methods include the
20 *Limulus* amoebocyte lysate (LAL) test or a monocyte activation test (MAT).

21
22 *A.4.1.3.10 Residual process-related contaminants*

23
24 The levels of residual process-related contaminants in the purified polysaccharide (for
25 example, CTAB, formaldehyde or other bacterial inactivating agent, and antifoaming agents)
26 should be determined, and shown to be below the limits agreed with the NRA. The routine
27 testing of each lot before release for residual process-related contaminants may be omitted
28 once consistency of production has been demonstrated on a number of lots; this number
29 should be agreed with the NRA.

30
31 *A.4.1.4 Activated polysaccharide*

32
33 Purified Vi polysaccharide is usually activated to enable conjugation; it may also be partially
34 depolymerized or fragmented, either before or during the activation process.

35
36 *A.4.1.4.1 Chemical activation*

37
38 Several methods are satisfactory for the chemical activation modification of Vi
39 polysaccharides prior to conjugation. The method that is chosen should be approved by the
40 NRA. As part of the in-process control procedures, the processed Vi polysaccharide that will
41 be used in the conjugation reaction should be assessed to determine the number of functional
42 groups introduced.

43

1 *A.4.1.4.2 Molecular size or mass distribution*

2
3 If any size-reduction or activation steps are performed, the average size or mass distribution
4 (that is, the degree of polymerization) of the processed Vi polysaccharide should be measured
5 using a suitable method. The size or mass distribution should be controlled using appropriate
6 limits as these may affect the reproducibility of the conjugation process as well as the
7 immunogenicity of the conjugate.

9 **A.4.2 Control of carrier protein production**

10
11 A protein that is safe and, when covalently linked with polysaccharide, elicits a T-cell-
12 dependent immune response against polysaccharide could potentially be used as a carrier
13 protein. Suitable carrier proteins include, but are not limited to, TT, DT, CRM₁₉₇ and rEPA.

15 *A.4.2.1 Consistency of microbial growth for the carrier protein*

16
17 The consistency of the growth of the microorganisms used to prepare the carrier protein
18 should be demonstrated by parameters, such as growth rate, pH and the final yield of the
19 carrier protein.

21 *A.4.2.2 Characterization and purity of the carrier protein*

22
23 Carrier proteins should be assayed for purity and concentration and tested to ensure they are
24 nontoxic and appropriately immunogenic. All tests used to control the carrier protein should
25 be approved by the NRA.

26
27 Preparations of TT and DT should satisfy the relevant WHO recommendations (137, 138).
28 CRM₁₉₇ can be obtained from cultures of *Corynebacterium diphtheriae* C7/β197 (139) or
29 expressed recombinantly by genetically modified microorganisms (140). CRM₁₉₇ with a
30 purity of not less than 90% as determined by high-performance liquid chromatography
31 (HPLC) should be prepared by column chromatographic methods. Residual host cell DNA
32 content should be determined and results should be within the limits approved by the NRA
33 for the particular product. Testing for residual host cell DNA content may be omitted if
34 adequate validation data are available. When CRM₁₉₇ is produced in the same facility as DT,
35 tests should be carried out to distinguish the CRM₁₉₇ protein from the active toxin.

36
37 A test should be performed on the purified carrier protein to verify its identity. Mass
38 spectrometry or a suitable immunoassay or physicochemical assay could be performed as
39 appropriate and convenient.

40
41 Additionally, the carrier protein should be further characterized using appropriate
42 physicochemical methods, such as: (a) sodium dodecyl sulfate–polyacrylamide gel
43 electrophoresis (SDS–PAGE); (b) isoelectric focusing; (c) HPLC; (d) amino acid analysis; (e)

1 amino acid sequencing; (f) circular dichroism; (g) fluorescence spectroscopy; (h) peptide
2 mapping; or (i) mass spectrometry (141). Outcomes should be within the specifications of the
3 carrier protein that was used to prepare the TCV lots evaluated in the definitive clinical
4 studies used for licensing.

6 ***A.4.2.3 Degree of activation of the carrier protein***

8 Adipic acid dihydrazide (ADH) or other appropriate linkers, such as N-succinimidyl-3-(2-
9 pyridyldithio)-propionate, can be used to modify the carrier protein. The level of protein
10 modification should be monitored, quantified and be consistent. The use of an in-process
11 control may be required. The reproducibility of the method used for modification should be
12 validated.

14 The level of modification of the carrier protein by ADH can be assessed by determining the
15 amount of hydrazide; this can be achieved by using colorimetric reactions with 2,4,6-
16 trinitrobenzenesulfonic acid using ADH as a standard (142–144). Other suitable methods
17 include fluorescent tagging followed by HPLC or quadrupole time-of-flight mass
18 spectrometry.

20 **A.4.3 Conjugation and purification of the conjugate**

22 A number of methods of conjugation are in use and all involve multistep processes (130,
23 142–145). Prior to demonstrating the immunogenicity of the Vi conjugate vaccine in clinical
24 trials, both the method of conjugation and the control procedures should be established to
25 ensure the reproducibility, stability and safety of the conjugate.

27 The derivatization and conjugation processes should be monitored and analyzed for unique
28 reaction products. Residual unreacted functional groups or their derivatives are potentially
29 capable of reacting in vivo and may be present following the conjugation process. The
30 manufacturing process should be validated and the limits for unreacted activated functional
31 groups (those that are known to be clinically relevant) at the conclusion of the conjugation
32 process should be agreed with the NRA.

34 After the conjugate has been purified, the tests described below should be performed to
35 assess the consistency of the production process. These tests are critical for ensuring
36 consistency from lot to lot.

38 **A.4.4 Control of the purified bulk conjugate**

40 Tests for releasing purified bulk conjugate should be validated.

42 ***A.4.4.1 Identity***

1 A suitable immunoassay or other method should be performed on the purified bulk conjugate
2 to verify the identity of the Vi polysaccharide. Depending on the buffer used, NMR
3 spectroscopy may be used to confirm the identity and integrity of the polysaccharide in the
4 purified bulk conjugate (133, 146–148). The identity of the carrier protein should also be
5 verified using an immunoassay or other suitable method.

6 7 **A.4.4.2 Endotoxin**

8
9 The endotoxin content of the purified bulk conjugate should be determined using a suitable in
10 vitro method (such as a LAL test or MAT) unless otherwise justified and shown to be within
11 limits agreed with the NRA.

12 13 **A.4.4.3 O-acetyl content**

14
15 The O-acetyl content of the purified bulk conjugate should be determined by NMR, Hestrin
16 method or other appropriate methods. The specification for the O-acetyl content of the
17 purified bulk conjugate should be agreed with the NRA. The specification for O-acetyl
18 content of the conjugate bulk should not be higher than that set for the purified Vi
19 polysaccharide.

20 21 **A.4.4.4 Residual reagents and process impurities**

22
23 The purification procedures for the conjugate should remove any residual reagents that were
24 used for conjugation and capping. The removal of reagents, their derivatives and reaction by-
25 products such as ADH, phenol and 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (known
26 as EDC, EDAC or EDCI) should be confirmed using suitable tests or by validation of the
27 purification process. The routine testing of each lot may be omitted once consistency of
28 production has been demonstrated on a number of lots; this number should be agreed with the
29 NRA.

30
31 The specifications of the residual reagents and the quantifiable methods to be used should be
32 agreed upon in consultation with the NRA.

33
34 Process validation should also demonstrate that no significant covalent modification of the Vi
35 polysaccharide itself has occurred, and the percentage of modified Vi monosaccharides
36 should not exceed what was shown to be safe and immunogenic in clinical studies. An
37 example of this is the use of EDC, which leads to N-acylurea modifications. The N-acylurea
38 content can be readily measured using NMR.

39 40 **A.4.4.5 Polysaccharide content**

41
42 The content of Vi polysaccharide should be determined using an appropriate validated assay
43 such as HPAEC-PAD (90, 113, 130, 131) or immunological methods (for example, rate

1 nephelometry, rocket electrophoresis). For recommendations on suitable reference materials
2 to use see **International reference materials** above.

3 4 ***A.4.4.6 Conjugated and unbound (free) polysaccharide***

5
6 A limit for the presence of unbound (free) Vi polysaccharide relative to total Vi
7 polysaccharide should be set for the purified bulk conjugate; this limit should be agreed with
8 the NRA. Methods that have been used to assay unbound polysaccharide include size-
9 exclusion chromatography–reverse phase liquid chromatography (149), Capto Adhere anion-
10 exchange resin binding (150) and deoxycholate precipitation (151) followed by HPAEC-PAD
11 or other method listed in section A 4.4.5 above. Other suitable methods may be developed
12 and validated.

13 14 ***A.4.4.7 Total protein and unbound (free) protein***

15
16 The protein content of the purified bulk conjugate should be determined using an appropriate
17 validated assay. Each batch should be tested for conjugated and unbound protein. The
18 unbound protein content of the purified bulk conjugate should comply with the limit for the
19 product that has been agreed with the NRA. Appropriate methods for determining unbound
20 protein include HPLC and capillary electrophoresis.

21 22 ***A.4.4.8 Conjugation markers***

23
24 The success of the conjugation process can be assessed by characterizing the conjugate using
25 suitable methods. For example, an increase in the MW of the protein component of the
26 conjugate compared with the carrier protein can be demonstrated using the Coomassie blue
27 stain with SDS–PAGE; an increase in the MW of the conjugate compared with both the Vi
28 polysaccharide and the protein components should be demonstrated by the gel filtration
29 profile, HPSEC, capillary electrophoresis or other suitable method.

30
31 Where the chemistry of the conjugation reaction results in the creation of a unique linkage
32 marker (for example, a unique amino acid, a linker or other measurable marker of
33 conjugation) this should be quantified for each conjugate batch to assess the extent of the
34 covalent reaction between the Vi polysaccharide and the carrier protein (145). This
35 assessment of the unique linkage marker may be omitted once the consistency of conjugation
36 is established, with the agreement of the NRA.

37 38 ***A.4.4.9 Absence of reactive functional groups***

39
40 The validation batches should be shown to be free of reactive functional groups or their
41 derivatives that are suspected to be clinically relevant on the polysaccharide and the carrier
42 protein.

43

1 Where possible, the presence of reactive functional groups (for example, those derived by
2 ADH treatment) should be assessed for each batch. Alternatively, the product of the capping
3 reaction may be monitored, or the capping reaction can be validated to show that reactive
4 functional groups have been removed.

6 ***A.4.4.10 Ratio of polysaccharide to carrier protein***

8 The ratio of polysaccharide to carrier protein in the purified bulk conjugate should be
9 calculated. For this ratio to be a suitable marker of conjugation, the content of each of the
10 conjugate components prior to their use should be known. For each purified bulk conjugate,
11 the ratio should be within the range approved by the NRA for that particular conjugate and
12 should be consistent with the ratio in vaccine that has been shown to be effective in clinical
13 trials.

15 ***A.4.4.11 Molecular size or mass distribution***

17 It is important to evaluate the molecular size or mass of the polysaccharide–protein conjugate
18 to establish the consistency of production, product homogeneity and stability during storage.

20 The relative molecular size of the polysaccharide–protein conjugate should be determined for
21 each purified bulk conjugate using a gel matrix appropriate for the size of the conjugate (87).
22 The method used should be validated and should have the specificity required to distinguish
23 the polysaccharide–protein conjugate from other components that may be present (for
24 example, unbound protein or polysaccharide). The specification of molecular size or mass
25 distribution should be vaccine specific and consistent with that of lots shown to be
26 immunogenic in clinical trials.

28 Typically, the size of the polysaccharide–protein conjugate may be examined by methods
29 such as gel filtration using HPSEC on an appropriate column. Since the ratio of
30 polysaccharide to protein is an average value, characterization of this ratio over the molecular
31 size or mass distribution (for example, by using dual monitoring of the column eluent) can
32 provide further proof of the consistency of production (141, 152).

34 ***A.4.4.12 Bacterial and fungal sterility***

36 The purified bulk conjugate should be tested for bacterial and fungal sterility according to the
37 methods described in Part A, sections 5.1 and 5.2 of the WHO General requirements for the
38 sterility of biological substances (153), or using methods approved by the NRA. If a
39 preservative has been added then appropriate measures should be taken to prevent it from
40 interfering with the tests.

42 ***A.4.4.13 Specific toxicity of the carrier protein***

1 The purified bulk conjugate should be tested to confirm the absence of toxicity specific to the
2 carrier protein where appropriate (for example, when DT or TT is used as the carrier protein).
3 Alternatively, the absence of specific toxicity of the carrier protein may be demonstrated at
4 the purified carrier protein stage if agreed with the NRA.

6 ***A.4.4.14 pH***

7
8 The pH of each batch should be tested, and the results should be within the established range
9 and compatible with stability data.

11 ***A.4.4.15 Appearance***

12
13 The appearance of the purified bulk conjugate solution, with respect to its form and colour,
14 should be examined by a suitable method and should meet the established specifications. For
15 a Vi polysaccharide conjugated to a toxoid, the appearance is typically clear to moderately
16 turbid, and colourless to pale yellow.

17
18 For a dried or lyophilized preparation, the appearance should be checked after reconstitution
19 with the appropriate diluent and should meet the established specifications.

21 **A.4.5 Preparation and control of the final bulk**

23 ***A.4.5.1 Preparation***

24
25 The final bulk is prepared by mixing a preservative or stabilizer, or both, with a suitable
26 quantity of the purified bulk conjugate to meet the specifications of vaccine lots that have
27 been shown to be safe and efficacious in clinical trials. If an adjuvant is used, it should be
28 mixed with the final bulk at this stage. The use of a preservative in either single-dose or
29 multi-dose vaccine vials is optional. If a preservative has been added, its effect on
30 antigenicity and immunogenicity must be assessed to ensure that the preservative does not
31 affect the immune response.

33 ***A.4.5.2 Test for bacterial and fungal sterility***

34
35 Each final bulk should be tested for bacterial and fungal sterility according to the methods
36 described in Part A, sections 5.1 and 5.2 of the WHO General requirements for the sterility of
37 biological substances (153), or using methods approved by the NRA. If a preservative has
38 been added to the final bulk, appropriate measures should be taken to prevent it from
39 interfering with the tests.

41 **A.5 Filling and containers**

1 The relevant guidance provided in WHO good manufacturing practices for pharmaceutical
2 products: main principles (118) and WHO good manufacturing practices for biological
3 products (119) should be followed.

4 5 **A.6 Control of the final product**

6 7 **A.6.1 Inspection of the final containers**

8
9 All filled final containers should be inspected as part of the routine manufacturing process.
10 Those containers showing abnormalities – such as vial defects, improper sealing, clumping or
11 the presence of endogenous or exogenous particles – should be discarded. The test should be
12 performed against a black, and a white, background, and according to pharmacopoeial
13 specifications.

14 15 **A.6.2 Control tests on the final lot**

16
17 The following tests should be performed on each final lot of vaccine (that is, in the final
18 container) and the tests used should be validated and approved by the NRA. The permissible
19 limits for tests listed under this section should be justified and approved by the NRA.

20 21 **A.6.2.1 Appearance**

22
23 The appearance of the final container and its contents should be verified using a suitable
24 method and should meet the established criteria with respect to form and colour. For freeze-
25 dried vaccines, their appearance should be verified before and after reconstitution, and should
26 meet the established criteria.

27 28 **A.6.2.2 Identity**

29
30 Identity tests on the Vi polysaccharide and the carrier protein should be performed on each
31 final lot. An immunological test or a physicochemical assay may be used for the Vi
32 polysaccharide and the carrier protein.

33 34 **A.6.2.3 Bacterial and fungal sterility**

35
36 The contents of the final containers should be tested for bacterial and fungal sterility
37 according to the methods described in Part A, sections 5.1 and 5.2 of the WHO General
38 requirements for the sterility of biological substances (153), or using a method approved by
39 the NRA.

40 41 **A.6.2.4 Polysaccharide content**

42

1 The amount of Vi polysaccharide conjugate in the final containers should be determined and
2 shown to be within the specifications agreed with the NRA.

3
4 The formulations of conjugate vaccines produced by different manufacturers may differ. A
5 quantitative assay for the Vi polysaccharide should be carried out. The specification should
6 be justified based on the clinical lots shown to be safe and immunogenic, and approved by
7 the NRA. Examples of tests that may be used include: (a) colorimetric methods; (b)
8 chromatographic methods (including HPLC and HPAEC-PAD); and (c) immunological
9 methods (including rate nephelometry and rocket immunoelectrophoresis) as discussed in
10 sections A.4.1.3.3 and A.4.4.5 of these Recommendations.

11 12 ***A.6.2.5 Unbound (free) polysaccharide***

13
14 A limit for free Vi polysaccharide content should be set for each conjugate vaccine as
15 discussed in section A.4.4.6 above. Assessing the level of unconjugated polysaccharide in the
16 final lot may be technically demanding (150); as an alternative, the molecular size of the
17 conjugate could be determined for the final lot to confirm the integrity of the conjugate. A
18 more-quantitative assessment of free Vi in solution can be performed by HPAEC-PAD
19 following separation of the intact conjugate. An acceptable value should be consistent with
20 the value seen in batches used for clinical trials that showed adequate immunogenicity and
21 should be approved by the NRA.

22 23 ***A.6.2.6 O-acetyl content***

24
25 The *O*-acetyl content of the Vi polysaccharide conjugate in the final container should be
26 determined for each final lot by NMR (127) or by other appropriate methods, such as the
27 Hestrin method (129). Routine release testing of each lot for *O*-acetyl content in the final
28 product may be omitted if:

- 29
- 30 ▪ the NRA agrees; and
 - 31 ▪ the *O*-acetyl content is measured at the level of conjugate bulk; and
 - 32 ▪ process-validation data obtained during the product's development confirm that
33 formulation and filling do not alter the integrity of the functional groups.

34
35 The specification for the *O*-acetyl content of the final lot should not be higher than that set for
36 the conjugate bulk. A limit for the *O*-acetyl content of the Vi polysaccharide conjugate
37 should be approved by the NRA (132).

38 39 ***A.6.2.7 Molecular size or mass distribution***

40
41 The molecular size or mass distribution of the polysaccharide–protein conjugate should be
42 determined for each final lot using a gel matrix appropriate for the size of the conjugate. The
43 analysis of molecular size or mass distribution for each final lot may be omitted provided that

1 the NRA agrees and the test has been performed on the conjugate bulk (see section A.4.4.11
2 above).

4 ***A.6.2.8 Endotoxin***

5
6 The endotoxin content of the final product should be determined using a suitable in vitro
7 assay such as a LAL test or MAT. The endotoxin content should be consistent with levels
8 found to be acceptable in vaccine lots used in clinical trials and within the limits agreed with
9 the NRA.

11 ***A.6.2.9 Adjuvant content and degree of adsorption***

12
13 If an adjuvant has been added to the vaccine, its content should be determined using a method
14 approved by the NRA. The amount of the adjuvant should also be agreed with the NRA. If
15 aluminium compounds are used as adjuvants, the amount of aluminium should not exceed
16 1.25 mg per single human dose.

17
18 The consistency of adsorption of the antigen to the adjuvant is important; the degree of
19 adsorption should be tested in each final lot and should be within the range of values
20 measured in vaccine lots shown to be clinically effective. The methods and specifications
21 used should be approved by the NRA.

23 ***A.6.2.10 Preservative content***

24
25 If a preservative has been added to the vaccine, its content should be determined using a
26 method approved by the NRA.

27
28 The amount of preservative in each dose of the vaccine should be shown not to have any
29 deleterious effect on the antigen or to impair the safety of the product in humans. The
30 effectiveness of the preservative should be demonstrated, and the concentration used should
31 be approved by the NRA.

33 ***A.6.2.11 pH***

34
35 If the vaccine is a liquid preparation, the pH of each final lot should be tested, and the results
36 should be within the range of values approved by the NRA. For a lyophilized preparation, the
37 pH should also be measured after reconstitution with the appropriate diluent.

39 ***A.6.2.12 Moisture content***

40
41 If the vaccine is a lyophilized preparation, the level of residual moisture should be
42 determined, and the results should be within the limit agreed with the NRA.

43

1 **A.6.2.13 Osmolality**
2

3 The osmolality of the final lots should be determined and shown to be within the range
4 considered to be safe for intramuscular administration to humans and agreed with the NRA.
5 The test for osmolality may be omitted once consistency of production is demonstrated or
6 justification is provided, with the agreement of the NRA.
7

8 **A.6.2.14 Protein content**
9

10 The protein content should be determined using an appropriate and validated assay. Routine
11 release testing of each lot for protein content in the final product may be omitted if the NRA
12 agrees.
13

14 **A.6.3 Control of diluents**
15

16 The general guidance provided in WHO good manufacturing practices for pharmaceutical
17 products: main principles (118) should be followed during the manufacture and quality
18 control of the diluents used to reconstitute TCVs. An expiry date should be established for the
19 diluents based upon stability data. For lot release of the diluent, tests should be done to assess
20 its appearance, identity, volume and sterility, and the concentrations of its key components.
21

22 **A.7 Records**
23

24 The relevant guidance provided in WHO good manufacturing practices for pharmaceutical
25 products: main principles (118) and WHO good manufacturing practices for biological
26 products (119) should be followed as appropriate for the level of development of the vaccine.
27

28 **A.8 Samples**
29

30 A sufficient number of lot samples of the product should be retained for future studies and
31 needs. Vaccine lots that are to be used for clinical trials may serve as reference materials in
32 the future and a sufficient number of vials should be reserved and stored appropriately for
33 that purpose.
34

35 **A.9 Labelling**
36

37 The guidance on labelling provided in WHO good manufacturing practices for biological
38 products (119) and WHO good manufacturing practices for biological products (119) should
39 be followed as appropriate and the label on the cartons enclosing one or more final
40 containers, or the leaflet accompanying each container, should include:
41

- 42
 - a statement that the vaccine fulfils Part A of these WHO Recommendations;

- 1 ▪ the instruction that any vaccine in a lyophilized form should be used immediately
- 2 after reconstitution; if data have been provided to the licensing authority indicating
- 3 that the reconstituted vaccine may be stored for a limited time then the length of time
- 4 should be specified;
- 5 ▪ where needed, information on the volume and nature of the diluent to be added to
- 6 reconstitute the lyophilized vaccine; this information should specify that the diluent
- 7 approved by the NRA should be supplied by the vaccine manufacturer; and
- 8 ▪ for multi-dose vials, the storage conditions and shelf-life after opening.

10 A.10 Distribution and transport

11
12 The guidance provided in WHO good manufacturing practices for pharmaceutical products:
13 main principles (118) and WHO good manufacturing practices for biological products (119)
14 should be followed.

15
16 Shipments should be maintained within specified temperature ranges, and packages should
17 contain cold-chain monitors. Further guidance on these and related issues is provided in the
18 WHO Model guidance for the storage and transport of time- and temperature-sensitive
19 pharmaceutical products (154).

21 A.11 Stability testing, storage and expiry date

22
23 The relevant guidance provided in WHO good manufacturing practices for biological
24 products (119) should be followed. Any statements concerning storage temperature and
25 expiry date that appear on primary or secondary packaging should be based on experimental
26 evidence and should be approved by the NRA.

28 A.11.1 Stability testing

29
30 Adequate stability studies form an essential part of vaccine development. These studies
31 should follow the general principles outlined in the WHO Guidelines on stability evaluation
32 of vaccines (155) and WHO Guidelines on the stability evaluation of vaccines for use under
33 extended controlled temperature conditions (156). The shelf-life of the final product and the
34 hold time of each process intermediate (such as the purified polysaccharide, the carrier
35 protein and the purified bulk conjugate) should be established based on the results of real-
36 time, real-condition stability studies, and approved by the NRA.

37
38 The stability of the vaccine in its final container and at the recommended storage temperature
39 should be demonstrated to the satisfaction of the NRA on at least three lots of the final
40 product manufactured from different bulk conjugates. In addition, a real-time real-condition
41 stability study should be conducted on at least one final container lot produced each year.

42

1 A protocol should be established and followed for each stability study which specifies the
2 stability-indicating parameters to be monitored, as well as the applicable specifications. Some
3 stability-indicating parameters may change over the shelf-life as discussed below. The
4 specifications should take into consideration the expected quality of the vaccine at the end of
5 shelf-life and should be linked to lots demonstrated to be safe and effective/immunogenic in
6 clinical trials. For vaccines intended for use under extended controlled temperature
7 conditions, the manufacturer should refer to the WHO Guidelines on the stability evaluation
8 of vaccines for use under extended controlled temperature conditions (156).

9
10 The polysaccharide component of conjugate vaccines may be subject to gradual hydrolysis at
11 a rate that may vary depending upon the type of conjugate, the formulation or adjuvant, the
12 excipient and the conditions of storage. The hydrolysis may result in reduced molecular size
13 of the Vi polysaccharide component, a reduction in *O*-acetyl content, a reduction in the
14 amount of polysaccharide bound to the carrier protein, a change in pH, reduced molecular
15 size of the conjugate, or some combination of these.

16
17 If applicable, the residual moisture should be monitored as part of stability testing and release
18 testing.

19
20 Where applicable, the level of adsorption of the conjugate to the adjuvant should be shown to
21 be within the limits agreed with the NRA, unless data show that the immunogenicity of the
22 final product does not depend on the adsorption of the antigen to the adjuvant.

23
24 Accelerated stability studies may provide additional supporting evidence of the stability of
25 the product or other product characteristics, or both, but are not recommended for
26 establishing the shelf-life of the vaccine under a defined storage condition.

27
28 When any changes are made in the production process that may affect the stability of the
29 product, the vaccine produced by the new method should be shown to be stable.

30 31 **A.11.2 Storage conditions**

32
33 The recommended long-term storage conditions should be based on the findings of the
34 stability studies and should ensure that all stability-indicating parameters of the conjugate
35 vaccine (for example, free saccharide) meet the required specifications at the end of the shelf-
36 life. The labelled and packaged vaccine products should be stored at the recommended long-
37 term storage conditions.

38
39 If approved by the NRA, the use of a vaccine under extended controlled temperature
40 conditions requires specific monitoring as described in the WHO Guidelines on the stability
41 evaluation of vaccines for use under extended controlled temperature conditions (156).

42

1 **A.11.3 Expiry date**

2
3 The expiry date should be based on the shelf-life as supported by stability studies and
4 approved by the NRA. The start of the dating period (for example, the date of formulation of
5 final bulk or the date of filling) should be agreed with the NRA. The expiry dates for vaccine
6 and diluent may be different from one another. If the vaccine and diluent are packaged
7 together, the expiry date for the package should be that of the component with the earliest
8 expiry date.

10 **A.11.4 Expiry of reconstituted vaccine (if applicable)**

11
12 For single-dose containers the reconstituted vaccine should be used immediately. For multi-
13 dose containers the use of the reconstituted container should follow the WHO multi-dose vial
14 policy¹, and this should be reflected in the package insert and supplied instructions.

16 **Part B. Nonclinical evaluation of typhoid conjugate vaccines**

18 **B.1 General principles**

19
20 Detailed WHO guidelines on the design, conduct, analysis and evaluation of nonclinical
21 studies of vaccines are available separately (157) and should be read in conjunction with Part
22 B of these WHO Recommendations. Plans for nonclinical studies of candidate vaccines
23 should be discussed with the NRA prior to the review process.

25 **B.2 Product characterization and process development**

26
27 It is critical that vaccine production processes are appropriately standardized and controlled
28 to ensure consistency in manufacturing and the collection of nonclinical data that may
29 suggest safety and efficacy in humans.

30
31 Candidate formulations of Vi conjugate vaccines should be characterized to define the critical
32 structural and chemical attributes that indicate that the polysaccharide, the conjugating
33 protein and the conjugate product are sufficiently pure and stable, and their properties are
34 consistent. The extent of product characterization may vary depending on the stage of vaccine
35 development. Vaccine lots used in nonclinical studies should be adequately representative of
36 those intended for use in clinical investigations. Ideally, the lots used should be the same as
37 those used in the clinical studies. If this is not feasible then the lots should be comparable
38 with respect to physicochemical data, stability and formulation.

1 B.3 Nonclinical immunogenicity studies

2
3 The immunogenicity of glycoconjugate vaccines can vary greatly between different animal
4 species and between strains within a species. Therefore, animal models used for
5 immunogenicity studies during glycoconjugate vaccine development programmes should be
6 selected with care as they may be poorly predictive of efficacy in humans. Animal studies
7 should only be conducted when they provide proof-of-concept information in support of a
8 clinical development plan, and any animal testing plan used in vaccine development should
9 incorporate 3Rs (Replace, Reduce, Refine) best practices.

10
11 Immunogenicity data derived from appropriately selected animal models may be useful in
12 establishing the immunological characteristics of the Vi polysaccharide conjugate product,
13 and may guide the selection of doses, schedules and routes of administration to be evaluated
14 in clinical trials. When animal models are used for the preclinical testing of vaccine
15 immunogenicity, they should elicit an anti-Vi IgG response that is significantly greater than
16 that of the control group (for example, a group that receives unconjugated Vi polysaccharide
17 vaccine). It should be noted that a booster response may not be observed following a second
18 dose if the priming dose induced a maximal response. Therefore, a good understanding of the
19 dose-immunogenic response should be established prior to evaluating any booster effect.

20
21 Immunogenicity studies have demonstrated that Vi polysaccharide conjugates induce anti-Vi
22 IgG in mice (102, 130, 158–161). In humans, high levels of anti-Vi IgG are associated with
23 greater levels of protection against typhoid infection (90, 91, 94) – although there is no
24 agreement that this may be considered a true correlate or surrogate of protection. Based on
25 these observations, the level of anti-Vi IgG elicited in mice may be considered as a primary
26 end-point for nonclinical studies of the immunogenicity of Vi conjugate vaccines.

27
28 Nonclinical studies of immunogenicity may include an evaluation of seroconversion rates or
29 geometric mean antibody titres, or both. When possible, nonclinical studies should be
30 designed to assess relevant immune responses, including functional immune response (for
31 example, by evaluating serum bactericidal antibodies, opsonophagocytic activity and serum-
32 dependent opsonophagocytic killing). These studies may also address the interference that
33 can occur among antigens when multi-antigen vaccines are used. In such cases, the response
34 to each antigen should be evaluated.

35
36 Although there have been advances in the use of animal models, no ideal animal model exists
37 that establishes direct serological or immunological correlates of clinical protection. In the
38 absence of such a model, it is important to ensure consistency of production using modern
39 physical, chemical and immuno-based quality-control methods as described in Part A of these
40 WHO Recommendations. Additionally, any changes in critical quality attributes should be
41 assessed for their impact on immunogenicity. Once the physicochemical tests are validated,
42 these non-animal methods are considered more appropriate for use in lot release processes
43 than animal models.

1

2 B.4 Nonclinical toxicity and safety studies

3

4 The WHO guidelines on nonclinical evaluation of vaccines (157) should be followed when
5 assessing toxicity and safety in an appropriate animal model. These studies should entail
6 careful analysis of all major organs, as well as of tissues proximal to and distal from the site
7 of administration, to detect unanticipated direct toxic effects. If the target population for the
8 vaccine includes pregnant women, or women of childbearing age, developmental toxicity
9 studies should also be considered unless there is a scientific and clinically sound justification
10 showing that conducting such studies is unnecessary (157).

11

12 Dose-response studies may not be necessary as the nonclinical evaluation of potential toxicity
13 can be performed at a dose that maximizes both the exposure of the animal and the
14 subsequent immune response (such as antibody titre). This dose can be determined during
15 pilot dose-response and/or immunogenicity studies. The dosing frequency and schedule
16 should be the same as, or greater than, the number of administrations intended in clinical
17 studies (157).

18

19 Requirements for the toxicity testing of individual vaccine components or any novel proteins
20 may vary between regulatory jurisdictions. These requirements should be scientifically
21 justified as individual vaccine components may have different toxicity and safety profiles
22 when present in the formulated product. Therefore, manufacturers are encouraged to discuss
23 these testing requirements with the NRA prior to commencing nonclinical studies.

24

25 Nonclinical safety studies should be conducted in accordance with the good laboratory
26 practices described elsewhere (162, 163). For ethical reasons, it is desirable to apply the 3Rs
27 concept of “Replace, Reduce, Refine” to minimize the use of animals in research where
28 scientifically appropriate.

29

30 **Part C. Clinical evaluation of typhoid conjugate vaccines**

31

32 C.1 General considerations

33

34 The general principles described in the WHO Guidelines on clinical evaluation of vaccines:
35 regulatory expectations (2) apply to Vi conjugate vaccines and should be followed. In
36 addition, a number of issues specific to the clinical development programme for Vi conjugate
37 vaccines are discussed below. The WHO Guidelines for good clinical practice (GCP) for
38 trials on pharmaceutical products (164) are also available and should be consulted.

39

40 Vi conjugate vaccines have now been licensed in some countries for use in children aged 6
41 months or older and in adults up to 45 years of age, with one such vaccine having been
42 prequalified by WHO (17). The licensure of effective Vi conjugate vaccines in some
43 countries and their availability through the WHO prequalification programme have

1 implications for the pathway to approval and design of clinical studies in children above the
2 age of 6 months and adults up to 45 years old. Information supporting the safety,
3 immunogenicity, efficacy and effectiveness of Vi conjugate vaccines in typhoid endemic
4 regions, as well as insights into putative immune correlates of protection, are continually
5 emerging (26, 88, 165–168). The principles for clinical evaluation outlined below are based
6 on the current situation and should be read in light of the circumstances obtaining in the
7 jurisdiction of the individual NRA.
8

9 C.2 Outline of the clinical development programme

10
11 It is recommended that the major part of the pre-licensure clinical development programme is
12 conducted in subjects who are representative of the intended target population.
13

14 C.2.1 Dose and schedule

15
16 The early clinical development programme should provide a preliminary assessment of safety
17 and should be suitable for identifying an appropriate dose of conjugated Vi antigen and dose
18 regimen(s) for the target age group(s). Such studies are necessary for each candidate Vi
19 conjugate vaccine that is developed since it is not possible to extrapolate the dose and
20 schedule identified for one conjugate vaccine to another. This consideration applies even if
21 the same carrier protein is used for two different Vi conjugate vaccines since experience with
22 other conjugated polysaccharide vaccines has indicated that differences in conjugation
23 chemistry can affect immune responses to the polysaccharide(s).
24

25 In the absence of a pre-licensure efficacy study, pathways to approval of a candidate Vi
26 conjugate vaccine in the jurisdiction of any one NRA may depend on the following:
27

- 28 ▪ If there is a licensed Vi conjugate vaccine for which protective efficacy has been
29 documented (the data may come from pre- and/or post-licensure efficacy studies
30 and/or from post-licensure studies of effectiveness), and subject to any pertinent
31 national legislation, the efficacy of a candidate Vi conjugate vaccine may be inferred
32 based on adequately designed comparative immunogenicity studies to bridge to the
33 efficacy data for the licensed vaccine.
- 34 ▪ If there are data that point to a specific anti-Vi antibody concentration that strongly
35 correlates with efficacy, the efficacy of a candidate Vi conjugate vaccine may be
36 inferred by estimating the proportion of baseline seronegative subjects with post-
37 vaccination immune responses that exceed the concentration identified. In this
38 situation, it may still be appropriate for an NRA to request that the sponsor compares
39 the immune response to the candidate vaccine with the immune response to a
40 licensed Vi conjugate vaccine for which protective efficacy has been demonstrated.
- 41 ▪ If there is no widely accepted antibody concentration that strongly correlates with
42 efficacy and no licensed Vi conjugate vaccine for which protective efficacy has been
43 documented, it may be appropriate to infer the efficacy of a candidate Vi conjugate

1 vaccine by comparing the immune response with a licensed unconjugated Vi
2 polysaccharide vaccine in subjects aged 2 years and above. For further details see
3 section C.4 below.

4 5 C.3 Assessment of the immune response

6 7 **C.3.1 Immune parameters of interest**

8
9 There are no well-established or standardized assays for assessing functional antibody
10 responses to Vi-containing vaccines, and it is not known how the results of such assays
11 correlate with vaccine efficacy.

12
13 Assessment of the immune response to licensed unconjugated (82, 169, 170) and conjugated
14 (26, 89, 90, 171) Vi polysaccharide vaccines has predominantly relied upon ELISA methods
15 to measure total anti-Vi IgG in serum. For unconjugated Vi polysaccharide vaccines,
16 approval has often been based on directly comparing the proportion of subjects that achieves
17 anti-Vi IgG of at least 1 µg/mL and/or the proportion that achieves at least a 4-fold increase
18 in anti-Vi IgG from pre- to post-vaccination. A regional or in-house working reference serum
19 preparation calibrated against the First WHO International Standard for anti-typhoid capsular
20 Vi polysaccharide IgG (human) (see **International reference materials** above) should be
21 used in the interpretation of immunogenicity data from clinical trials. The use of this WHO
22 international standard improves consistency in the determination of serum titres and provides
23 a basis for the comparison of data generated by different assays and/or different laboratories.

24
25 At present, there is no established or widely agreed immune correlate of protection for
26 typhoid vaccines – though correlations between total serum antibody (79), total anti-Vi IgG
27 (81, 92, 93, 172, 173) or anti-Vi IgA (97) in serum and protection against typhoid have been
28 described. A putative immune correlate of protection based on anti-Vi IgG has been proposed
29 based on long-term follow-up of Vietnamese children who received a candidate Vi conjugate
30 vaccine in a large efficacy trial. However, the value reported is specific to the assay that was
31 applied during that study and it is not yet clear what the corresponding values may be when
32 using alternative assays.

33 34 **C.3.2 Considerations regarding the carrier protein**

35
36 Proteins such as CRM₁₉₇, DT, TT and rEPA have been used in the production of various Vi
37 conjugate vaccines. Based on experience with other types of conjugate vaccines that use
38 CRM₁₉₇, DT or TT as the carrier protein, there is a possibility that the immune response to
39 the Vi conjugated antigen may be reduced or enhanced in subjects who have pre-existing
40 high levels of tetanus or diphtheria antitoxin before vaccination. This phenomenon should be
41 explored during the development of Vi conjugate vaccines; this may be accomplished by
42 analysing post-vaccination responses and comparing these with pre-vaccination antibody

1 concentrations to the protein carrier. The potential clinical significance of any effect requires
2 careful consideration.

3
4 Depending on the target age range, it may be important to assess the effects of co-
5 administering Vi conjugate vaccines with other routine vaccinations. Guidance on such
6 studies, including instances in which co-administered vaccines contain the carrier protein,
7 may be found in the WHO Guidelines on clinical evaluation of vaccines: regulatory
8 expectations (2).

10 **C.3.3 Immune memory**

11
12 Vi conjugate vaccines are expected to elicit T-cell-dependent immune responses, which can
13 be assessed by administration of a post-priming Vi conjugate dose after an interval of at least
14 6–12 months. Details of the clinical assessment of priming may be found in the WHO
15 Guidelines on clinical evaluation of vaccines: regulatory expectations (2). Whether or not
16 booster doses will be needed to maintain protection after successful priming with Vi
17 conjugate vaccines is not yet known. Until this issue is resolved, plans should be put in place
18 to document antibody persistence and to evaluate vaccine effectiveness.

20 **C.4 Immunogenicity**

21
22 This section should be read in conjunction with the guidance on comparative immunogenicity
23 trials provided in the WHO Guidelines on clinical evaluation of vaccines: regulatory
24 expectations (2). The selection of the most appropriate licensed vaccine for use as a
25 comparator in clinical studies must be agreed between the sponsor and the NRA.

27 **C.4.1 Studies that compare conjugated Vi polysaccharide vaccines**

28
29 If the aim of the study is to immunobridge efficacy documented with a licensed Vi conjugate
30 vaccine to a candidate vaccine, the study should be designed to demonstrate the non-
31 inferiority of the immune response elicited by the candidate vaccine when compared with a
32 licensed Vi conjugate vaccine. The primary immune parameter for the purposes of
33 immunobridging and the acceptance criteria for concluding that the candidate vaccine will
34 have at least similar efficacy to the licensed vaccine should be predefined and agreed between
35 the sponsor and the NRA.

36
37 If efficacy data have supported the derivation of an immune correlate of protection, the
38 proportion of subjects that achieves at least this concentration after vaccination with the
39 candidate vaccine should be the primary immune parameter. In this case, a direct comparison
40 with a licensed Vi conjugate vaccine would not be essential though some NRAs may request
41 that a comparison is made with a licensed Vi conjugate vaccine for which vaccine efficacy
42 has been documented to provide a comparison of safety.

43

1 If the sponsor wishes, or is requested, to conduct a comparative study against a licensed Vi
2 conjugate vaccine for which efficacy is not documented then demonstrating non-inferiority
3 for the candidate versus licensed vaccine does not evidence the potential efficacy of the
4 candidate vaccine. Therefore, either the immune responses to the candidate vaccine should be
5 interpreted against an immune correlate of protection or threshold value or, if neither exists,
6 consideration should be given to alternative study designs as described below.

7 8 **C.4.2 Studies that compare Vi conjugate vaccines with unconjugated Vi** 9 **polysaccharide vaccines**

10
11 Studies that compare candidate Vi conjugate vaccines with licensed unconjugated Vi
12 polysaccharide vaccines should only be conducted in subjects who are at least 2 years of age.
13 It is recommended that such studies are conducted only if a licensed Vi conjugate vaccine
14 comparator is not available and it is considered important to generate comparative safety and
15 immunogenicity data versus a licensed vaccine (see section C.2 above). If such studies are to
16 be the basis for approval, data should be generated for the age range for which a claim for use
17 of the candidate vaccine will be sought. Studies should stratify subjects by appropriate age
18 subgroups, or separate studies should be conducted in different age groups.

19
20 For potential approaches to the primary comparison of immune responses see section C.3
21 above.

22
23 The immune responses should be measured in samples collected at day 28 after the initial
24 vaccination series has been completed (that is, after a single dose or after the last assigned
25 dose of the primary series) or in samples collected at an alternative time point if this is
26 justified by data on antibody kinetics.

27 28 **C.4.3 Studies that compare vaccinated groups with unvaccinated or control groups** 29

30 There are two situations in which such studies may be considered:

- 31
- 32 ▪ As explained in section C.2 above, if there is an established immune correlate of
33 protection, a direct comparison of immune responses with a licensed vaccine is not
34 necessary. However, such a comparison may still be useful for interpreting the safety
35 data and for putting the immune responses to the candidate vaccine into context.
 - 36 ▪ In the absence of an immune correlate of protection or the possibility of
37 immunobridging the candidate Vi conjugate vaccine to the protective efficacy of a
38 licensed Vi conjugate vaccine, a study that compares a candidate Vi conjugate
39 vaccine with an unvaccinated group could be considered for subjects under 2 years of
40 age. A comparison between a candidate Vi conjugate vaccine and a licensed
41 unconjugated Vi polysaccharide vaccine would not be appropriate due to lack of
42 reliable protective immune responses to the latter in children under 2 years of age. In
43 this situation, it is recommended that studies are based upon randomized allocation to

1 the candidate Vi conjugate vaccine (that is, the vaccinated group) or to a licensed
2 non-typhoid vaccine from which study subjects may derive some benefit (that is, the
3 control group).

4
5 In both of the above situations, the anti-Vi immune responses in the group receiving the
6 candidate Vi conjugate vaccine should be superior to those in the unvaccinated or control
7 group. To put the immune responses observed into context, the anti-Vi titres elicited by the
8 candidate Vi conjugate vaccine in children under 2 years of age may be compared (either
9 directly or in a cross-study comparison) with one or both of:

- 10
11 ▪ the immune response to an unconjugated Vi polysaccharide vaccine in subjects
12 ≥ 2 years of age;
13 ▪ the immune response to the candidate Vi conjugate vaccine in subjects ≥ 2 years of
14 age.

15 16 C.5 Efficacy

17
18 This section should be read in conjunction with the guidance on efficacy trials and
19 effectiveness studies provided in the WHO Guidelines on clinical evaluation of vaccines:
20 regulatory expectations (2).

21
22 Protective efficacy studies against typhoid can be conducted only in endemic areas with
23 relatively high rates of disease. If a protective efficacy study is conducted, it should compare
24 the rates of febrile illnesses associated with a positive blood culture for *S. Typhi* between a
25 group that receives the candidate Vi conjugate vaccine and an appropriate control group.

26
27 Successful typhoid challenge studies conducted in healthy adults using an appropriate and
28 validated model (that is, one in which some protective efficacy of unconjugated Vi
29 polysaccharide vaccines is detectable) could provide considerable supporting evidence of the
30 efficacy of a Vi conjugate vaccine. Human challenge studies may provide information on the
31 relationship between the immune response and various efficacy parameters. If, in
32 consultation with the NRA, sponsors decide to conduct typhoid challenge studies in humans,
33 they should be undertaken only by physicians with appropriate expertise, and in a carefully
34 controlled setting, to ensure the safety of the volunteers (109). Healthy adults that are
35 expected or known to be naive to typhoid and typhoid vaccines should be screened to detect
36 any underlying pre-existing conditions that could impact on safety. In particular, subjects
37 who might be at risk of complications of typhoid should be excluded, including any subject
38 with gall bladder disease. The challenge strain should be well characterized and there should
39 be complete information available on its susceptibility to antibacterial agents.

40
41 An issue to consider after initial licensure is the possibility that widespread use of a Vi
42 conjugate vaccine and high vaccination coverage in a population in which typhoid fever is

1 endemic may lead to the emergence of otherwise rare Vi-negative variants of *S. Typhi* (174–
2 177); such variants exist and can cause typhoid fever, albeit at lower attack rates (110, 111).

3 4 C.6 Safety

5
6 Current evidence suggests there are no major specific safety issues for Vi conjugate vaccines
7 (178) and that reports of adverse events are similar to those of other polysaccharide–protein
8 conjugate vaccines. It is recommended that the assessment of safety in pre-licensure studies
9 should follow the usual approaches to ensure comprehensive monitoring and data collection
10 (2). When considering the pre-licensure safety database, the need for a sufficient sample size
11 to estimate adverse event rates with precision is an important factor. For example, a total
12 database of 3000 subjects across all trials and populations provides a 95% chance of
13 observing one instance of an adverse event that occurs on average in 1 in every 1000 subjects
14 (179). Other considerations include the type of conjugative protein used in the candidate Vi
15 conjugate vaccine and the extent of clinical experience with similar conjugated vaccines.

16 17 **Part D. Recommendations for NRAs**

18 19 D.1 General recommendations

20
21 The guidance for NRAs and national control laboratories given in the WHO Guidelines for
22 national authorities on quality assurance for biological products (120) and WHO Guidelines
23 for independent lot release of vaccines by regulatory authorities (180) should be followed.
24 These guidelines specify that no new biological substance or product should be released until
25 consistency of batch manufacturing and quality has been established and demonstrated by the
26 manufacturer.

27
28 The detailed production and control procedures, as well as any significant changes in them
29 that may affect the quality, safety or efficacy of the Vi conjugate vaccine, should be
30 discussed with and approved by the NRA. For control purposes, the relevant international
31 reference preparations currently in force should be obtained for the purpose of calibrating
32 national, regional and working standards as appropriate. The NRA may obtain from the
33 manufacturer the product-specific or working reference to be used for lot release.

34
35 Consistency of production has been recognized as an essential component in the quality
36 assurance of Vi conjugate vaccines. The NRA should carefully monitor production records
37 and quality control test results for clinical lots, as well as for a series of consecutive lots of
38 the final bulk and final product.

39 40 D.2 Official release and certification

41
42 A vaccine lot should be released only if it fulfils all national requirements and/or satisfies
43 Part A of these WHO Recommendations (180).

1
2 A summary protocol for the manufacturing and control of typhoid conjugate vaccines, based
3 on the model summary protocol provided in Appendix 1 and signed by the responsible
4 official of the manufacturing establishment, should be prepared and submitted to the NRA in
5 support of a request for the release of a vaccine for use. This protocol may also be referred to
6 as the Product Specification File.

7
8 A lot release certificate signed by the appropriate NRA official should then be provided if
9 requested by the manufacturing establishment, and should certify that the lot of vaccine meets
10 all national requirements and/or Part A of these WHO Recommendations. The certificate
11 should provide sufficient information on the vaccine lot. The purpose of this official national
12 lot release certificate is to facilitate the exchange of vaccines between countries and should be
13 provided to importers of the vaccines. A model certificate for the lot release of typhoid
14 conjugate vaccines is provided below in Appendix 2.

15 16 **Authors and acknowledgements**

17
18 The scientific basis for the revision of the WHO Guidelines on the quality, safety and
19 efficacy of typhoid conjugate vaccines (*1*) was discussed at a WHO drafting group meeting
20 held in Potters Bar, the United Kingdom on 25–26 November 2019 and attended by: Dr B.
21 Bolgiano, National Institute for Biological Standards and Control, the United Kingdom; Dr I.
22 Feavers, Consultant, Nacton, the United Kingdom; Dr F. Gao, National Institute for
23 Biological Standards and Control, the United Kingdom; Dr E. Griffiths, Consultant, Kingston
24 upon Thames, the United Kingdom; Dr M. Levine, University of Maryland School of
25 Medicine, Baltimore, MD, the USA; Dr J.L. Mathew, Postgraduate Institute of Medical
26 Education and Research, India; Dr L. Parsons, United States Food and Drug Administration,
27 the USA; Dr A. Pollard, University of Oxford, the United Kingdom; Dr S. Rijpkema,
28 National Institute for Biological Standards and Control, the United Kingdom; Dr T. Wu,
29 Health Canada, Canada; and Dr A.D. Bentsi-Enchill, Dr R. Isbrucker, Dr I. Knezevic and Dr
30 S-H. Yoo, World Health Organization, Switzerland. The first draft of the current document
31 was then prepared by the above drafting group, which also included Dr M. Powell, Health
32 Products Regulatory Authority, Ireland. Comments received from Dr L.B. Martin, GSK
33 Vaccines Institute for Global Health, Italy; and Dr P. Talaga, Dr E. Zablackis and Dr S.
34 Gaudin, Sanofi Pasteur, Lyons, France and Swiftwater, PA, USA were also addressed.

35
36 The draft document was then posted on the WHO Biologicals website for public consultation
37 from 6 April 2020 to 6 May 2020. Comments were received from: Dr V. Bansal, Central
38 Drugs Laboratory, India; Dr B. Bolgiano, Dr F. Gao and Dr S. Rijpkema, National Institute
39 for Biological Standards and Control, the United Kingdom; Dr Z. Diaz, Dr L-F. Ma, Dr C.
40 MacLennon and Dr D. Steele, Bill and Melinda Gates Foundation, Seattle, WA, the USA; Dr
41 S. Gairola, Serum Institute of India PVT. Ltd, India; Dr K.P. Gonzalez, Dr L.R. Ariza and Dr
42 S.M.M. Sanchez, Instituto Nacional de Vigilancia de Medicamentos y Alimentos, Colombia;
43 Dr J. Lim, National Institute of Food and Drug Safety Evaluation, Republic of Korea; Dr K.

1 Maithal, Cadila Healthcare Ltd, India; Mr S.D. Prasad, Bharat Biotech International Ltd,
2 India; Mr D. Ugiyadi and Mr Y. Sofyan, PT Bio Farma (Persero), Indonesia; and Dr M. Alali
3 and Dr A. Fauconnier, World Health Organization, Switzerland. Consolidated comments on
4 behalf of members of the International Federation of Pharmaceutical Manufacturers &
5 Associations, Switzerland were also received from Ms P. Barbosa.

Appendix 1

Model summary protocol for the manufacturing and control of typhoid conjugate vaccines

The following protocol is intended for guidance and indicates the minimum information that should be provided by the manufacturer to an NRA. Information and tests may be added or omitted as required by the NRA.

It is possible that a protocol for a specific product may differ in detail from the model provided. The essential point is that all relevant details demonstrating compliance with the licence and with the relevant WHO recommendations for a particular product should be given in the protocol submitted.

The section concerning the final product must be accompanied by a sample of the label and a copy of the leaflet that accompanies the vaccine container. If the protocol is being submitted in support of a request to permit importation, it must also be accompanied by a certificate for the release of typhoid conjugate vaccines from the NRA of the country in which the vaccine was produced (see Appendix 2) stating that the product meets national requirements as well as the recommendations in Part A of this document.

1. Summary information on final lot:

International name of product: _____

Commercial name: _____

Product licence (marketing authorization) number: _____

Country: _____

Name and address of manufacturer: _____

Nature of final product: _____

Final packing lot number: _____

Number of containers in this packing lot: _____

Type of container: _____

Final container lot number: _____

Number of filled containers in the final lot: _____

Number of doses per final container: _____

Volume of each recommended single human dose: _____

Preservative used and nominal concentration: _____

1 Summary of composition (*include a summary of the qualitative and quantitative composition*
 2 *of the vaccine per single human dose; including the conjugate, any adjuvant used and other*
 3 *excipients*):

4 _____
 5 _____

6
 7
 8 Shelf-life approved (months): _____

9 Date of manufacture: _____

10 Expiry date: _____

11 Storage conditions: _____

12

13

14 **2. Detailed information on manufacture and control**

15

16 *The following sections are intended for reporting the results of the tests performed during the*
 17 *production of the vaccine, so that the complete document will provide evidence of consistency*
 18 *in production; thus, if any test had to be repeated, this information must be indicated. Any*
 19 *abnormal results should be recorded on a separate sheet.*

20

21 **Summary of source materials**

22

23 It is possible that a number of bulk lots may be used to produce a single final lot. A summary
 24 of the bulk polysaccharide, activated saccharide, bulk carrier protein and bulk conjugate lots
 25 that contributed to the final lot should be provided.

26

27 **Control of typhoid Vi polysaccharide**

28

29 **Bacterial strain**

30 Identity of bacterial strain used

31 (e.g. *Salmonella* Typhi Ty2 or *Citrobacter freundii*): _____

32 Origin and short history: _____

33 Authority that approved the strain: _____

34 Date approved: _____

35

36 **Bacterial culture media for seed-lot preparation and Vi production**

37 Free from ingredients that form precipitate when CTAB is added: _____

38 Free from toxic or allergenic substances: _____

39 Any components of animal origin (list): _____

40 Certified as TSE-free: _____
