Organization**

WHO/GBS/DRAFT2/PC2/MAY2026
ENGLISH ONLY

**Guidelines on the quality, safety and efficacy of group B
streptococcal conjugate vaccines**
(Proposed new guidelines)

NOTE:

The distribution of this draft document is intended to provide information on the proposed document- *Guidelines on the quality, safety and efficacy of group B Streptococcal conjugate vaccines*, to a broad audience and to ensure the transparency of the consultation process.

Written comments proposing modifications to this text MUST be received by 19 June 2026 in the Comment Form available separately and should be addressed to the World Health Organization, 1211 Geneva 27, Switzerland, attention: Department of Medicines and Health Products Policies and Standards. Comments may also be submitted electronically to the Responsible Officer: **Dr Tiequn Zhou at email: zhout@who.int**.

The final agreed formulation of the document will be edited to be in conformity with the second edition of the *WHO Style Guide* (KMS/WHP/13.1).

Guidelines published by the World Health Organization (WHO) are intended to be scientific and advisory in nature. Each of the following sections constitutes guidance for national regulatory authorities (NRAs) and for manufacturers of biological products. If an NRA so desires, these WHO Guidelines may be adopted as definitive national requirements, or modifications may be justified and made by the NRA. It is recommended that modifications to these Guidelines are made only on condition that such modifications ensure that the product is at least as safe and efficacious as that prepared in accordance with the guidance set out below.

13
14

1 Abbreviations

2		
3	ADH	adipic acid dihydrazide
4	CRM197	cross-reactive material 197
5	CTAB	hexadecyltrimethylammonium bromide
6	DT	diphtheria toxoid
7	EDC	1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (also abbreviated to
8		EDAC)
9	EOD	early onset disease
10	GBS	group B streptococcus (<i>Streptococcus agalactiae</i>)
11	HIV	human immunodeficiency virus
12	HPAEC-PAD	high-performance anion exchange chromatography with pulsed
13		amperometric detection
14	HPLC	high-performance liquid chromatography
15	HPSEC	high-performance size-exclusion chromatography
16	IAP	intrapartum antibiotic prophylaxis
17	IgG	immunoglobulin G
18	LOD	late onset disease
19	MAT	monocyte activation test
20	NCL	national control laboratory
21	NMR	nuclear magnetic resonance
22	NRA	national regulatory authority
23	OPA	opsonophagocytic antibody
24	rCR	recombinant cascade response
25	rFC	recombinant factor C
26	TT	tetanus toxoid
27		

1 Introduction

2
3 Group B streptococcal (GBS) disease, caused by the bacterium *Streptococcus agalactiae*,
4 occurs most commonly as neonatal sepsis and meningitis, with a disproportionate burden of
5 morbidity and mortality in low- and middle-income countries (LMICs) (1). Antibiotic
6 prophylaxis given to women in labour (intra-partum antibiotic prophylaxis [IAP]) can be
7 effective in preventing early onset GBS disease in neonates but its use has implications for
8 antimicrobial resistance and IAP is poorly implemented in many countries (2). Maternal
9 vaccination has long been proposed as an alternative to IAP and GBS vaccines are amongst the
10 priority vaccines identified by WHO Product Development for Vaccines Advisory Committee
11 (3,4). In addition, GBS disease is identified as a key target for vaccine development in the
12 WHO *Defeating Meningitis by 2030* roadmap (5).

13 Multivalent GBS capsular polysaccharide–protein conjugate vaccines are at an
14 advanced stage of clinical development. Evidence indicates that they induce vaccine serotype-
15 specific immune responses in pregnant women (6-8). Recognizing the challenges of conducting
16 sufficiently powered pre-licensure efficacy trials for maternal GBS vaccines in a reasonable
17 timeframe, efforts have been made to identify serotype-specific immune correlates of
18 protection against invasive GBS disease in neonates and infants (8) using standardized
19 immunoassays and harmonized reference materials (8).

20 Acknowledging the global impact of GBS disease, the WHO Expert Committee on
21 Biological Standardization (ECBS) has expressed its support for the production of written
22 standards to facilitate GBS vaccine development. At its 81st meeting in October 2025, the
23 ECBS agreed to prioritize the development of WHO Guidelines on the quality, safety and
24 efficacy of GBS capsular polysaccharide-protein conjugate vaccines (9).

25 These recommendations provide guidance for the production and control of GBS
26 capsular polysaccharide-protein conjugate vaccines in Part A and for their nonclinical
27 evaluation in Part B. Part C covers the clinical development programme for GBS capsular
28 polysaccharide-protein conjugate vaccines intended to prevent invasive GBS infections in
29 neonates and infants by means of vaccinating pregnant women. These recommendations reflect
30 technological advances including the removal of animal testing from quality control schemes
31 (10,11).

32 Purpose and scope

33
34
35 These WHO Guidelines provide guidance for national regulatory authorities (NRAs) and
36 vaccine manufacturers on the quality, nonclinical and clinical aspects of human group B
37 streptococcal (GBS) capsular polysaccharide-protein conjugate vaccines to assure their quality,
38 safety and efficacy. The scope of the present document encompasses prophylactic GBS
39 capsular polysaccharide-protein conjugate vaccines intended for immunization of women in
40 the late second or third trimesters of pregnancy with the primary aim of preventing early onset
41 GBS disease (EOD) in neonates and late onset GBS disease (LOD) in neonates and infants.

42 This document should be read in conjunction with other relevant WHO guidance,
43 especially on the nonclinical (12,13) and clinical (14) evaluation of vaccines, as well as the

1 minimum requirements for an effective National Pharmacovigilance System (15). Other WHO
2 guidance should also be consulted as appropriate.

3 Several protein-based GBS vaccines, including candidates intended to elicit immune
4 responses to conserved proteins, are also under evaluation (7). Candidate GBS vaccines that
5 are not based on elicitation of anti-capsular antibody are not within the scope of the present
6 document. Currently, sponsors developing such vaccines should consult the WHO (12, 13, 14)
7 and other applicable regulatory guidance documents. As the scientific evidence base and
8 regulatory experience evolves, additional WHO guidance may be developed as appropriate.

9 It should be noted that there remain knowledge gaps in the scientific understanding of
10 GBS vaccines which are being addressed by ongoing research and development. This
11 document has been developed in the light of the available knowledge.

13 Terminology

14
15 The definitions given below apply to the terms as used in these WHO Guidelines. These terms
16 may have different meanings in other contexts.

17 **Activated polysaccharide:** purified polysaccharide that has been modified by a
18 chemical reaction or a physical process in preparation for conjugation to the carrier protein.

19 **Carrier protein:** the protein to which the polysaccharide is covalently linked for the
20 purpose of eliciting a T-cell-dependent immune response to the GBS polysaccharide.

21 **Final bulk:** The blend of monovalent conjugates present in a single container from
22 which the final containers are filled, either directly or through one or more intermediate
23 containers derived from the initial single container.

24 **Final lot:** a number of sealed, final containers that are equivalent with respect to the
25 risk of contamination that may have occurred during filling and, when it is performed, freeze-
26 drying. A final lot must therefore have been filled from a single container and if freeze-dried
27 this should be completed in one continuous working session.

28 **Master seed lot:** bacterial suspensions for the production of serotype specific GBS
29 polysaccharide or the carrier protein should be derived from a strain that has been processed as
30 a single lot and is of uniform composition. The master seed lot is used to prepare the **working**
31 **seed lots**. Master seed lots should be maintained in the freeze-dried form or be frozen at or
32 below -45°C .

33 **Monovalent bulk conjugate:** a conjugate prepared from a single lot or pool of lots of
34 polysaccharide and a single lot or a pool of lots of protein by the covalent bonding of activated
35 polysaccharide to the carrier protein. This is the parent material from which the **final bulk** is
36 prepared.

37 **Purified polysaccharide:** the material obtained after final purification of
38 polysaccharide. The lot of purified polysaccharide may be derived from a **single harvest** or a
39 pool of single harvests that have been processed together.

40 **Single harvest:** the material obtained from one batch of culture that has been inoculated
41 with the **working seed lot** (or with the inoculum derived from it), harvested and processed
42 during one production run.

1 **Working seed lot:** a quantity of bacterial suspension for the production of GBS
2 polysaccharide or the carrier protein that is of uniform composition and that has been derived
3 from the **master seed lot** by growing the organisms and maintaining them in freeze-dried
4 aliquots or frozen at or below -45°C . The working seed lot is used to inoculate the production
5 medium.

6 7 **General considerations**

8 9 ***Group B streptococcus (Streptococcus agalactiae)***

10
11 *Streptococcus agalactiae* is the most common human pathogen among the streptococci
12 belonging to Lancefield group B. However, in most people it is a harmless commensal
13 bacterium that commonly colonises the gastrointestinal and genitourinary tracts (16).

14 Historically, *Streptococcus agalactiae* was classified into nine serotypes according to
15 capsular polysaccharides (Ia, Ib, II, III, IV, V, VI, VII, VIII) but a tenth (IX) was identified in
16 2007 (17, 18). The capsular polysaccharides enable GBS to evade the host's immune system
17 while their heterogeneity contributes to serotype-associated variability in disease severity (17,
18 18). A review of studies that reported GBS serotypes isolated from cases of invasive GBS
19 disease in infants indicated that 97% were serotypes Ia, Ib, II, III and V. Serotype III dominated
20 (61.5%). No or few data were available from some geographical regions (19).

21 22 ***Invasive GBS disease***

23
24 Invasive GBS is the leading cause of neonatal sepsis and meningitis worldwide and an
25 important cause of meningitis in early infancy (19-22). Invasive GBS disease in neonates and
26 infants is described according to its time of onset. Early-onset disease (EOD) occurs within the
27 first six days of life and usually occurs due to vertical transmission from GBS-colonised
28 mothers. Late onset disease (LOD) occurs between 7 and 89 days after birth and GBS may be
29 acquired from the mother or may result from nosocomial or community infections.

30 It was estimated that in 2020 approximately 20 million pregnant women globally were
31 colonised with GBS, leading to more than 230,000 cases of EOD and more than 160,000 cases
32 of LOD annually (2). These cases were estimated to be associated with approximately 90,000
33 deaths resulting from deliveries without a skilled birth attendant. Infants who survive may
34 develop sequelae such as neurodevelopmental impairment (23, 24).

35 GBS is also associated with adverse outcomes of pregnancy (e.g. stillbirth and preterm
36 birth), maternal systemic infections during pregnancy or labour and invasive infections in older
37 adults, especially in those with diabetes or cancer (25-27).

38 39 ***Prevention strategies***

40
41 The primary prevention strategy for GBS EOD in some countries is intrapartum antibiotic
42 prophylaxis (IAP). This is administered to women known to be colonised in late pregnancy
43 through microbiological screening, which requires adequate laboratory facilities, or to women

1 identified for receipt of IAP via other risk-based approaches (28, 29). Where used, IAP has
2 reduced the incidence of EOD, but it has not eliminated EOD, and it has no effect on LOD.
3 Furthermore, IAP raises concerns about increasing antimicrobial resistance in GBS and
4 disruption of the normal flora in neonates (30).

6 ***GBS vaccine development***

8 An association between placental transfer of maternal anti-capsular IgG antibodies and
9 protection from invasive GBS was first reported in the 1970s (31). These and later reports
10 pointed to the possibility of preventing GBS EOD and LOD by maternal immunization during
11 the last trimester of pregnancy when placental transfer of IgG is maximal (32, 33). While the
12 focus of GBS vaccine development is on the prevention of EOD and LOD in neonates and
13 infants, it is also possible that vaccination during pregnancy may reduce the risk of maternal
14 complications, stillbirth and preterm birth (30).

15 It has been estimated that a GBS capsular polysaccharide-protein conjugate vaccine
16 that includes serotypes Ia, Ib, II, III, V and VI could potentially prevent invasive GBS disease
17 caused by serotypes responsible for over 98% of global cases of EOD and LOD (34). However,
18 vaccine efficacy will depend not only on vaccine content but also on levels and persistence of
19 serotype-specific anti-capsular antibodies in neonates and infants and on the levels needed to
20 prevent invasive EOD or LOD due to each serotype. Furthermore, the initial effect of
21 vaccination on GBS EOD rates will vary according to whether IAP is also available and widely
22 implemented where routine maternal immunization is introduced.

23 Initial clinical trials in the 1980s tested candidate vaccines with purified native type Ia,
24 II or III polysaccharides that had limited immunogenicity (35). To improve immune responses
25 and to elicit immune memory, second-generation candidate vaccines used conjugation of
26 capsular polysaccharides to tetanus toxoid or to CRM197 carrier proteins (36-39). For example,
27 a trivalent CRM197-conjugated vaccine containing polysaccharides of serotypes Ia, Ib and III
28 demonstrated an acceptable safety profile and good immunogenicity in Phase 1 and 2 trials that
29 included pregnant women and women living with HIV (39). More recently, a GBS
30 polysaccharide-protein conjugate vaccine including six serotypes has been evaluated in clinical
31 trials (6).

33 ***Immune response to GBS as a basis for licensure***

35 Phase 3 placebo-controlled vaccine efficacy studies with invasive GBS disease as the primary
36 endpoint are predicted to require very large sample sizes and may take several years to
37 complete (40). For example, it has been estimated that such a trial with a primary endpoint of
38 invasive GBS disease in neonates and infants would require at least 60,000 pregnant women to
39 be enrolled in countries with a known incidence of >1:1000 live births. Even then, it may take
40 approximately 10 years to accrue sufficient cases to conduct a primary analysis that provides a
41 robust estimate of overall vaccine efficacy. In addition, even a very large trial may not provide
42 reliable estimates of efficacy for each serotype or for each of EOD and LOD. Furthermore, to
43 accrue sufficient cases in a reasonable timeframe such trials would probably have to be

1 conducted in areas where IAP is not standard of care, such that the estimate of efficacy against
2 EOD would not be applicable where IAP is routinely administered.

3 Given these constraints, NRAs may wish to consider the possibility that initial licensure
4 of GBS vaccines may be based on safety data and on immunogenicity data obtained from cord
5 blood of neonates born to women who were immunized in the late second or third trimester
6 (40). In this way, there would be inference of protection against invasive GBS disease based
7 on immune markers. In the absence of a pre-licensure efficacy trial and when there is no well-
8 established immune correlate of protection, it is usually preferred that inference of vaccine
9 efficacy based on immune markers is focused on levels of functional antibody (14). In the case
10 of GBS this would require measurement of opsonophagocytic antibody (OPA) titres (41, 42),
11 which would capture the total effect of naturally-acquired functional antibodies directed at
12 GBS capsular and sub-capsular antigens. Thus far, it has not been possible to establish OPA
13 titre threshold values that strongly correlate with risk of invasive GBS disease. Therefore, sero-
14 epidemiological studies have focused on identifying threshold values for cord blood anti-
15 capsular IgG that seem to be strongly associated with reductions in the risk of developing
16 invasive GBS EOD or LOD caused by specific serotypes (43-45).

17 Various studies have pointed to possible threshold IgG cord blood anti-capsular
18 antibody levels that might be strongly associated with reductions in risk of invasive GBS
19 disease. For example, a sero-epidemiological study conducted as part of a South African
20 vaccine trial reported a 75% risk reduction for invasive GBS due to serotype III when cord
21 blood IgG against this serotype was at least 0.15 µg/mL with an estimate across serotypes at
22 0.184 µg/mL (44). Subsequently, a study in Finland suggested that cord blood IgG values of
23 0.12 µg/mL for serotype III and 0.168 µg/mL across all serotypes were associated with a 75%
24 risk reduction for invasive GBS (46). More recently, a large sero-epidemiological study
25 conducted by the United States Centre for Diseases Control has reported IgG levels associated
26 75% risk reduction for EOD and LOD due to certain serotypes, including 0.27 µg/mL for
27 serotype III EOD and 0.03 µg/mL for serotype III LOD (47). Further sero-epidemiological
28 studies are ongoing or are still to report.

29 When considering possible threshold values of cord blood anti-capsular IgG it is
30 essential that attention is paid to the methodologies applied to collect and interpret sero-
31 epidemiological data (48) and the assays applied such that the selected threshold values of IgG
32 derived from reported studies are those that appear most reliable and relevant to individual
33 NRA jurisdictions.

34 In situations in which initial approval of a vaccine is based on safety and
35 immunogenicity data with application of threshold values associated with reduction in invasive
36 GBS disease incidence, it is especially important that NRAs are assured that there are adequate
37 plans in place at the time of licensure for the conduct of vaccine effectiveness studies (49).
38 Whenever the data collected allow, these post-approval studies should at least attempt to
39 estimate vaccine-associated reductions in the incidence of GBS disease due to individual
40 serotypes as well as against each of EOD and LOD. Wherever possible, these studies should
41 include collection of cord blood samples to allow further estimates of IgG concentrations that
42 correlate with protection as well as investigation of the possible relationship between OPA

1 titres and invasive GBS. These data may serve to support existing and/or point to new threshold
2 values that are serotype-specific and/or relevant to EOD and LOD.

4 **International reference materials**

6 Although no formally established international reference materials were available to support
7 the standardization of measurements of immune responses to GBS capsular polysaccharide-
8 protein conjugate vaccines at the time this document was prepared, proposals for their
9 development have been endorsed by ECBS (50,51). The use of such reference materials is
10 recommended upon their availability.

11 The following reagents are available from reference laboratories:

- 12 • GBS strains of serotypes Ia, Ib, II, III, IV, V, VI, VII, VIII and IX can be obtained from
13 the National Collection of Type Cultures (NCTC; UK Health Security Agency,
14 Colindale, London, United Kingdom) with the identification numbers (14094, 14092,
15 14093, 14091, 11930, 14095, 13947, 13949, 13948 and 13945 respectively).
- 16 • HL-60 cells, available from the American Type Culture Collection (ATCC; Manassas,
17 VA, USA) or the European Collection of Cell Cultures (ECACC; Porton Down,
18 Salisbury, England).

20 **Part A. Guidelines on the development, manufacture and control of group B** 21 **streptococcal conjugate vaccines**

22 **A.1 Definitions**

23 **A.1.1 International name and proper name**

24 The international name of the vaccine should be “group B streptococcal conjugate vaccine”
25 with additions to indicate the serotype(s) in the vaccine. The proper name should be the
26 equivalent of the international name in the language of the country in which the vaccine is
27 licensed.

28 The use of the international name should be limited to vaccines that meet the
29 specifications given below.

30 **A.1.2 Descriptive definition**

31 Multivalent GBS conjugate vaccine is a preparation of capsular polysaccharide from specific
32 serotypes of GBS that are covalently linked to carrier protein.

33 **A.2 General manufacturing requirements**

34 The general manufacturing recommendations contained in WHO Good manufacturing
35 practices for pharmaceuticals (52) and WHO Good manufacturing practices for biological

1 products (53) should be applied to establishments manufacturing GBS conjugate vaccines with
2 the addition of the following:

3 Details of standard operating procedures for the preparation and testing of GBS
4 conjugate vaccines adopted by the manufacturer, together with evidence of appropriate
5 validation of each production step, should be submitted for the approval of the NRA. All assay
6 procedures used for quality control of the conjugate vaccines and vaccine intermediates must
7 be validated. As may be required, proposals for the modification of manufacturing and control
8 methods should also be submitted for approval to the NRA before they are implemented.

9 Group B streptococci are Biosafety Level 2 (BSL-2) pathogens. The organism should
10 be handled under appropriate conditions for this class of pathogen (54). Standard operating
11 procedures need to be developed for dealing with emergencies arising from the accidental
12 spillage, leakage or other dissemination of bacteria. Personnel employed in the production and
13 control facilities should be adequately trained. Appropriate protective measures, including
14 vaccination, should be implemented if available. Adherence to current good manufacturing
15 practices is important to the integrity of the product, to protect workers and to protect the
16 environment.

17 A.3 Control of source materials

18 A.3.1 Control of polysaccharide

19 A.3.1.1 *Strains of group B streptococci*

20 The streptococcal strains used for preparing the polysaccharide constitute the master seed lot
21 and should be agreed with the NRA along with the tests used for their characterization. Each
22 strain should be from a single well-characterized stock that can be identified by a record of its
23 history, including the source from which it was obtained, number of passages and the tests used
24 to determine its characteristics. Each strain should have been shown to be capable of stably
25 producing polysaccharide of the appropriate serotype. Proton nuclear magnetic resonance (¹H
26 or ¹³C NMR) spectroscopy, immunochemical tests or any other suitable method may be used
27 for confirming the identity of the polysaccharide.

28 A.3.1.2 *Seed lot system*

29 The production of GBS polysaccharide should be based on a seed lot system, which includes
30 master seed and working seed lots. Cultures derived from the working seed lots should have
31 the same characteristics as the cultures of the strain from which the master seed lot was derived
32 (A.3.1.1). To ensure their stability, seed lots should be stored either freeze-dried or frozen in a
33 dedicated storage facility, as recommended in the WHO good manufacturing practices for
34 biological products (53). Wherever possible, manufacturers are encouraged to avoid the use of
35 materials of animal origin. If, however, materials of animal origin are used in the medium for
36 seed production, for preservation of strain viability for freeze-drying or for frozen storage, they
37 should comply with *WHO Guidelines on transmissible spongiform encephalopathies in
38 relation to biological and pharmaceutical products* (55) and should be approved by the NRA.

1 ***A.3.1.3 Culture media used to produce group B streptococcal polysaccharide***

2 The culture medium used to prepare bacterial seed lots and commercial vaccine lots should
3 also be free from substances likely to cause toxic or allergic reactions in humans. Additionally,
4 the liquid culture medium used for vaccine production should be free from ingredients that will
5 form a precipitate upon purification of the capsular polysaccharide. If materials of animal
6 origin are used, they should comply with *WHO Guidelines on transmissible spongiform*
7 *encephalopathies in relation to biological and pharmaceutical products* (55) and should be
8 approved by the NRA.

9 **A.4 Control of vaccine production**

10 **A.4.1 Control of polysaccharide antigen production**

11 ***A.4.1.1 Single harvests***

12 Consistency of streptococcal growth should be demonstrated by monitoring parameters such
13 as growth rate, pH, pO₂ and the final yield of polysaccharide; however, monitoring should not
14 be limited to these parameters.

15 ***A.4.1.2 Control of bacterial purity***

16 Samples of the culture should be taken before inactivation and be examined for microbial
17 contamination. The purity of the culture should be verified by suitable methods, which should
18 include inoculation on to appropriate culture media, including plate media that do not support
19 growth of GBS. If any contamination is found, the culture or any product derived from it should
20 be discarded. The inactivation process should also be adequately validated.

21 ***A.4.1.3 Purified polysaccharide***

22 Serotype-specific polysaccharides of GBS consist of three or four of the five sugars: glucose,
23 galactose, *N*-acetylglucosamine, rhamnose and sialic acid. The structures of the
24 polysaccharides corresponding to all ten recognized serotypes are described elsewhere (56).

25 Each lot of GBS polysaccharide should be tested for identity, purity and molecular size
26 using a combination of validated methods to provide all necessary data. Where appropriate,
27 specific compositional attributes and serogroup-specific antigens that may affect antigenicity
28 and immunogenicity should be controlled. These include the content and distribution of
29 distinctive chemical groups or epitopes (e.g., sialic acid, O-acetyl groups and N-acetyl groups)
30 and residual group B carbohydrates. Analytical characterization of these attributes can be
31 achieved using a combination of chemical assays, NMR (57,58) and HPAEC-PAD (59). Any
32 test limits or ranges not defined by a pharmacopoeia should be agreed with the NRA.

33 ***A.4.1.3.1 Polysaccharide identity***

34 A test should be performed on the purified polysaccharide to verify its identity, such as NMR
35 spectroscopy (57,58) or suitable immunoassay. In cases where other polysaccharides are
36 produced on the same manufacturing site, the method should be validated to show that it

1 distinguishes the desired polysaccharide from all other polysaccharides produced on that
2 manufacturing site.

3 *A.4.1.3.2 Polysaccharide content*

4 The polysaccharide content should be measured using a suitable, validated method agreed with
5 the NRA, such as ^1H or ^{13}C NMR (57,58) or HPAEC-PAD (59), a suitable chemical method,
6 or an immunochemical assay. Suitable polysaccharide reference preparations should be used
7 when appropriate

8 *A.4.1.3.3 Molecular size or mass distribution*

9 The molecular size or mass distribution of each lot of purified polysaccharide should be
10 estimated to assess the consistency of each batch. An acceptable level of consistency should
11 be agreed with the NRA and can be established either by process validation or by measurement
12 on each lot. Suitable methods include gel filtration or HPSEC with refractive index detectors
13 either alone or in combination with light scattering (60). The method and column used should
14 be validated to demonstrate sufficient resolution in the appropriate molecular weight range.

15 *A.4.1.3.4 Moisture content*

16 If the purified polysaccharide is to be stored as a lyophilized powder, the moisture content
17 should be determined by suitable methods approved by the NRA and shown to be within agreed
18 limits.

19 *A.4.1.3.5 Protein impurity*

20 The protein content should be determined using a suitable validated method, such as that of the
21 method of Lowry et al., using bovine serum albumin as a reference (61), or another suitable
22 validated method. Sufficient polysaccharide should be assayed to accurately detect protein
23 contamination. Each lot of purified polysaccharide should typically contain no more than 1%
24 (weight/weight) of protein. However, this may vary depending upon the serotype, and an
25 acceptable level of protein contamination should be agreed with the NRA.

26 *A.4.1.3.6 Nucleic acid impurity*

27 Each lot of polysaccharide should contain no more than 2% by weight of nucleic acid as
28 determined by ultraviolet spectroscopy – on the assumption that the absorbance of a 1 g/l
29 nucleic acid solution contained in a cell of 1 cm path length at 260 nm is 20 (62) or by another
30 validated method. Sufficient polysaccharide should be assayed to accurately determine nucleic
31 acid contamination.

32 *A.4.1.3.7 Pyrogen content*

33 The pyrogen content of the purified polysaccharide should be determined and shown to be
34 within acceptable limits agreed by the NRA. The test used should be based on an assessment
35 of the risk that the material is potentially contaminated with endotoxin or non-endotoxin
36 pyrogens. Where there is a risk of non-endotoxin pyrogens being present, the use of the

1 monocyte activation test (MAT) is recommended (63,64). In cases where non-endotoxin
2 pyrogens are unlikely to be present, endotoxin testing using the recombinant Factor C (rFC)
3 assay or the recombinant Cascade Response (rCR) assay is recommended (65).

4 *A.4.1.3.8 Residual process-related contaminants*

5 The levels of residual process-related contaminants in the purified polysaccharide (for example,
6 CTAB, formaldehyde or other bacterial inactivating agent, and antifoaming agents) should be
7 determined and shown to be below the limits agreed with the NRA. The routine testing of each
8 lot before release for residual process-related contaminants may be omitted once consistency
9 of production has been demonstrated on a number of lots agreed with the NRA.

10 *A.4.1.4 Modified polysaccharide*

11 Purified polysaccharide is usually activated to enable conjugation; it may also be partially
12 depolymerized or fragmented, either before or during the activation process.

13 *A.4.1.4.1 Chemical modification*

14 Several methods are satisfactory for the chemical activation modification of polysaccharides
15 prior to conjugation. The method that is chosen should be approved by the NRA.

16 *A.4.1.4.2 Extent of modification of the polysaccharide*

17 The manufacturer should demonstrate consistency of the degree of modification of the
18 polysaccharide, either by an assay of each batch of the polysaccharide or by validation of the
19 manufacturing process. Depending on the conjugation chemistry used, consistency in the
20 degree of polysaccharide activation may be determined as part of process validation and reflect
21 characteristics of vaccine lots shown to have adequate safety and immunogenicity in clinical
22 trials.

23 *A.4.1.4.3 Molecular size distribution*

24 If any size-reduction or activation steps are performed, the average size or mass distribution
25 (that is, the degree of polymerization) of the processed polysaccharide should be measured
26 using a suitable method and shown to be consistent. The molecular size distribution should be
27 specified for each serotype, with appropriate limits for consistency, as the size may affect the
28 reproducibility of the conjugation process.

29 **A.4.2 Control of the carrier protein**

30 A protein that is safe and, when covalently linked with polysaccharide, elicits a T-cell-
31 dependent immune response against polysaccharide can be used as a carrier protein. Suitable
32 carrier proteins include, but are not limited to, TT, DT and CRM197.

33 *A.4.2.1 Consistency of production of the carrier protein*

34

1 The manufacturing process for a carrier protein should be shown to consistently yield batches
2 that are suitable for the conjugation process. Adequate in-process control should be
3 implemented to monitor critical process parameters, such as the growth rate of the
4 microorganism, pH of production culture and the final yield of the carrier protein.

6 ***A.4.2.2 Characterization and purity of the carrier protein***

7
8 Carrier proteins should be assayed for purity and concentration and tested to ensure they are
9 nontoxic and appropriately immunogenic. All tests used to control the carrier protein should
10 be approved by the NRA.

11 Preparations of TT and DT should satisfy the relevant WHO recommendations (66,67).
12 CRM₁₉₇ can be obtained from cultures of *Corynebacterium diphtheriae* C7/β197 (68) or by
13 expression in other genetically modified microorganisms (69). CRM₁₉₇ with a purity of not
14 less than 90% as determined by high-performance liquid chromatography (HPLC) should be
15 prepared by column chromatographic methods. Residual host cell DNA content should be
16 measured and results should be within the limits approved by the NRA for the particular
17 product. Testing for residual host cell DNA content may be omitted if adequate validation data
18 are available. When CRM₁₉₇ is produced in the same facility as DT, tests should be carried
19 out to distinguish the CRM protein from the active toxin.

20 A test should be performed on the purified carrier protein to verify its identity. Mass
21 spectrometry or a suitable immunoassay or physicochemical assay could be performed as
22 appropriate and convenient.

23 Additionally, the carrier protein should be further characterized using appropriate
24 physicochemical methods, such as: (a) sodium dodecyl sulfate–polyacrylamide gel
25 electrophoresis (SDS–PAGE); (b) isoelectric focusing; (c) HPLC; (d) amino acid analysis; (e)
26 amino acid sequencing; (f) circular dichroism; (g) fluorescence spectroscopy; (h) peptide
27 mapping; or (i) mass spectrometry. Outcomes should be within the specifications of the carrier
28 protein that was used to prepare the lots evaluated in the definitive clinical studies used for
29 licensing.

31 ***A.4.2.3 Specific toxicity of carrier protein***

32
33 The purified carrier protein should be tested to confirm the absence of toxicity specific to the
34 carrier protein where appropriate (for example, when DT or TT is used as the carrier protein)
35 using a validated non-animal method where available (e.g. the Vero cell assay for DT).

37 ***A.4.2.4 Degree of activation of the carrier protein***

38
39 Adipic acid dihydrazide (ADH) or other appropriate linkers, such as N-succinimidyl-3-(2-
40 pyridyldithio)-propionate or hydrazine-polyethylene glycol-hydrazine linker (Hz-PEG-Hz
41 linker), can be used to modify the carrier protein (70). The level of protein modification should
42 be monitored, quantified and be consistent. The use of an in-process control may be required.
43 The reproducibility of the method used for modification should be validated.

1 The level of modification of the carrier protein by ADH can be assessed by determining
2 the amount of hydrazide; this can be achieved by using colorimetric reactions with 2,4,6-
3 trinitrobenzenesulfonic acid using ADH as a standard (71). Other suitable methods include
4 fluorescent tagging followed by HPLC or quadrupole time-of-flight mass spectrometry.

5 6 **A.4.3 Conjugation and purification of the conjugate**

7 Conjugation methods involve multistep processes. Prior to demonstrating the immunogenicity
8 of the vaccine in clinical trials, both the method of conjugation and the control procedures
9 should be established to ensure the reproducibility, stability and safety of the conjugate.

10 The derivatization and conjugation processes should be monitored and analyzed for
11 unique reaction products. Residual unreacted functional groups or their derivatives are
12 potentially capable of reacting in vivo and may be present following the conjugation process.
13 The manufacturing process should be validated and the limits for unreacted activated functional
14 groups (those that are known to be clinically relevant) at the conclusion of the conjugation
15 process should be agreed with the NRA.

16 After the conjugate has been purified, the tests described below should be performed to
17 assess the consistency of the production process. These tests are critical for ensuring lot to lot
18 consistency.

19 **A.4.4 Control of monovalent bulk conjugates**

20 ***A.4.4.1 Identity***

21 A test should be performed on the monovalent bulk to verify its identity of both the serotype-
22 specific polysaccharide and carrier protein. The method should be validated to show that it
23 distinguishes the desired monovalent material from all other polysaccharides and conjugates
24 produced on that manufacturing site.

25 ***A.4.4.2 Residual reagents***

26 The purification procedures for the conjugate should remove any residual reagents that were
27 used for conjugation and capping. The removal of reagents, their derivatives and reaction by-
28 products such as ADH, phenol and 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (known
29 as EDC, EDAC or EDCI) should be confirmed using suitable tests or by validation of the
30 purification process. The routine testing of each lot may be omitted once consistency of
31 production has been demonstrated on a number of lots; the number should be agreed with the
32 NRA. The specifications of the residual reagents and the quantifiable methods to be used
33 should be agreed with the NRA.

34 35 ***A.4.4.3 Polysaccharide content***

36 The polysaccharide content should be measured using an appropriate validated assay such as
37 HPAEC-PAD (59,72), specific chemical assay or immunological method (for example, rate
38 nephelometry, rocket electrophoresis).

1 ***A.4.4.4 Conjugated and unbound (free) polysaccharide***

2 Only the polysaccharide that is covalently bound to the carrier protein, i.e. conjugated
3 polysaccharide, is immunologically important for clinical protection. Each batch of conjugate
4 should be tested for unbound or free polysaccharide to establish consistency of production and
5 to ensure that the amount present in the purified bulk is within the limits agreed by the NRA
6 based on lots shown to be clinically safe and efficacious.

7 Methods that have been used to separate unbound polysaccharide before assay, and that
8 are potentially applicable to GBS conjugates, include hydrophobic chromatography, acid
9 precipitation, precipitation with carrier protein-specific antibodies, gel filtration and
10 ultrafiltration. The amount of unbound polysaccharide can be determined by specific chemical
11 or immunological tests, or by HPAEC after hydrolysis.

12 13 ***A.4.4.5 Total protein and unbound (free) protein***

14 The protein content of the purified bulk conjugate should be determined using an appropriate
15 validated assay. Each batch should be tested for conjugated and unbound protein. The unbound
16 protein content of the purified bulk conjugate should comply with the limit for the product that
17 has been agreed with the NRA. Appropriate methods for determining unbound protein include
18 HPLC and capillary electrophoresis.

19 ***A.4.4.6 Polysaccharide–protein ratio and conjugation markers***

20 For each batch of the bulk conjugate of each serotype, the ratio of polysaccharide to carrier
21 protein should be determined as a marker of the consistency of the conjugation chemistry. For
22 each conjugate, the ratio should be within the range approved for each serotype-specific
23 conjugate by the NRA and should be consistent with vaccine shown to be effective in clinical
24 trials.

25 If the chemistry of conjugation results in the creation of a unique linkage marker (e.g.
26 a unique amino acid), each batch of the bulk conjugate of that serotype should be assessed to
27 quantify the extent of substitution of the carrier protein by covalent reaction of the
28 polysaccharide with the carrier protein.

29 30 ***A.4.4.7 Absence of reactive functional groups***

31 The validation batches should be shown to be free of reactive functional groups or their
32 derivatives that are suspected to be clinically relevant on the polysaccharide and the carrier
33 protein.

34 Where possible, the presence of reactive functional groups should be assessed for each
35 batch. Alternatively, the product of the capping reaction may be monitored, or the capping
36 reaction can be validated to show that reactive functional groups have been removed.

37 ***A.4.4.8 Molecular size distribution***

38 The molecular size of the polysaccharide–protein conjugate is an important parameter in
39 establishing consistency of production and in studying stability during storage.

1 The relative molecular size of the polysaccharide–protein conjugate should be
2 determined for each bulk, using a gel matrix appropriate to the size of the conjugate. The
3 method should be validated with an emphasis on specificity to distinguish the polysaccharide–
4 protein conjugate from other components that may be present, e.g. unbound protein or
5 polysaccharide. The size distribution specifications will be vaccine-specific and should be
6 consistent with lots shown to be immunogenic in clinical trials.

7 Typically, the size of the polysaccharide–protein conjugate may be examined by methods
8 such as gel filtration using HPSEC on an appropriate column. Since the ratio of polysaccharide
9 to protein is an average value, characterization of this ratio over the molecular size or mass
10 distribution (for example, by using dual monitoring of the column eluent) can provide further
11 proof of the consistency of production (60).

12 ***A.4.4.9 Sterility***

13 The bulk purified conjugate should be tested for bacterial and mycotic sterility in accordance
14 with the methods of Part A, sections 5.1 and 5.2, of the revised WHO general requirements for
15 the sterility of biological substances (73) or by a method approved by the NRA. If a
16 preservative has been added to the product, appropriate measures should be taken to prevent it
17 from interfering with the test.

18 When appropriate controls, environmental monitoring and risk assessment are in place
19 for the manufacturing of the purified bulk conjugate in a low bioburden setting, testing for
20 sterility may be omitted and instead the bulk should be tested for bioburden with appropriate
21 limits approved by the NRA.

22 ***A.4.4.10 Endotoxin content***

23 To ensure an acceptable level of endotoxin in the final product, the endotoxin content of the
24 monovalent bulk may be determined and shown to be within acceptable limits agreed by the
25 NRA using an rFC or rCR assay.

26 ***A.4.4.11 pH***

27 The pH of each batch should be tested, and the results should be within the established range
28 and compatible with stability data.

30 ***A.4.4.12 Appearance***

31 The appearance of the purified bulk conjugate solution, with respect to its form and colour,
32 should be examined by a suitable method and should meet the established specifications. For
33 a lyophilized preparation, the appearance should be checked after reconstitution with the
34 appropriate diluent and should meet the established specifications.

35 **A.4.5 Final bulk**

36 ***A.4.5.1 Preparation***

37 To formulate the final bulk, monovalent conjugate bulks may be mixed and an adjuvant,
38 preservative and/or stabilizer added before final dilution. If a preservative is used, it should not

1 impair the quality, safety or potency of the vaccine; the intended concentration of the
2 preservative should be scientifically justified and its effectiveness appropriately validated.

3 Following dilution, and when applicable prior to adsorption on adjuvant, the final bulk
4 is subjected to sterile filtration. Pre-filtration bioburden should be monitored as part of in-
5 process controls.

6 Alternatively, the monovalent conjugate bulks may be adsorbed to adjuvant
7 individually before mixing them to formulate the final vaccine.

8 ***A.4.5.2 Sterility***

9 Each final bulk should be tested for bacterial and fungal sterility as indicated in section A.4.4.9.

10 **A.5 Filling and containers**

11 The relevant guidance provided in WHO good manufacturing practices for pharmaceutical
12 products: main principles (52) and WHO good manufacturing practices for biological products
13 (53) should be followed.

14 **A.6 Control of the final product**

15 **A.6.1 Inspection of the final containers**

16 All filled final containers should be inspected as part of the routine manufacturing process.
17 Those containers showing abnormalities – such as vial defects, improper sealing, clumping or
18 the presence of endogenous or exogenous particles – should be discarded.

19 **A.6.2 Control tests on the final lot**

20 The following tests should be performed on each final lot of vaccine (that is, in the final
21 container) and the tests used should be validated and approved by the NRA. The permissible
22 limits for tests listed under this section should be justified and approved by the NRA.
23

24 ***A.6.2.1 Appearance***

25 The appearance of the final container and its contents should be verified using a suitable
26 method and should meet the established criteria with respect to form and colour. For freeze-
27 dried vaccines, their appearance should be verified before and after reconstitution, and should
28 meet the established criteria. The test should be performed against a black, and a white,
29 background, and according to pharmacopoeial specifications.
30

31 ***A.6.2.2 Identity***

32 An identity test should be performed that demonstrates that all the intended polysaccharide
33 serotypes and carrier protein(s) are present in the final product, unless this test has been
34 performed on the final bulk.

35 ***A.6.2.3 Bacterial and fungal sterility***

1 The contents of the final containers should be tested for bacterial and mycotic sterility in
2 accordance with the methods of Part A, sections 5.1 and 5.2, of the revised WHO General
3 requirements for the sterility of biological substances (73) or by a method approved by the
4 NRA. If a preservative has been added to the product, appropriate measures should be taken to
5 prevent it from interfering with the test.

6 **A.6.2.4 Polysaccharide content**

7 The amount of each streptococcal polysaccharide in the final containers should be determined
8 and shown to be within the specifications agreed by the NRA. Conjugate vaccines produced
9 by different manufacturers may differ in formulation. The specification should be justified
10 based on the clinical lots shown to be safe and immunogenic, and approved by the NRA. The
11 assays used are likely to be product-specific and might include chromatographic or serological
12 methods.

13 **A.6.2.5 Unbound (free) polysaccharide**

14 A limit for free polysaccharide content should be set for each serotype included in the conjugate
15 vaccine as discussed in section A.4.4.4 above. Where serotype-specific quantitation of free
16 polysaccharide in a multivalent product is not feasible, manufacturers may specify total
17 polysaccharide and total free polysaccharide for the final container using validated assays. An
18 acceptable value should be consistent with the value seen for batches shown to be immunogenic
19 in clinical studies and should be agreed with the NRA.

20 **A.6.2.6 Residual moisture**

21 If the vaccine is freeze dried, the average moisture content should be determined by methods
22 accepted by the NRA. Values should be within the limits for the preparations shown to be
23 adequately stable in the stability studies of the vaccine.

24 **A.6.2.7 Endotoxin or pyrogen content**

25 The endotoxin content of the final product should be determined using a suitable in vitro assay
26 such as an rFC or rCR assay. The endotoxin content should be consistent with levels found to
27 be acceptable in vaccine lots used in clinical trials and within the limits agreed with the NRA.

28 The need to test for non-endotoxin pyrogens should be determined during the
29 manufacturing development process. It should also be evaluated following any changes in the
30 production process or relevant reported production inconsistencies that could influence the
31 quality of the product regarding its pyrogenicity. When required, the MAT should be used to
32 measure non-endotoxin pyrogens.

33 **A.6.2.8 Adjuvant content**

34 If an adjuvant has been added to the vaccine, its content and the degree of adsorption of the
35 antigen should be determined by methods approved by the NRA and be consistent with vaccine
36 lots shown to be immunogenic in clinical studies. The amount and nature of the adjuvant should
37 be agreed with the NRA. If aluminium compounds are used as adjuvants, the amount of
38 aluminium should not exceed 1.25 mg per single human dose.

1 **A.6.2.9 Preservative content**

2 If a preservative has been added to the vaccine, the content of preservative should be
3 determined by a method approved by the NRA. The amount of preservative in the vaccine dose
4 should be shown to be effective and not to have any deleterious effect on the antigen or to
5 impair the safety of the product in humans. The preservative and its concentration should be
6 approved by the NRA.

7 **A.6.2.10 pH**

8 If the vaccine is a liquid preparation, the pH of each final lot should be tested and shown to be
9 within the range of values found for vaccine lots shown to be safe and effective in clinical trials
10 and in stability studies. For a lyophilized preparation, the pH should be measured after
11 reconstitution with the appropriate diluent.

12 **A.6.2.11 Osmolality**

13 The osmolality of the final lots should be determined and shown to be within the range
14 considered to be safe for intramuscular administration to humans and agreed with the NRA.
15 The test for osmolality may be omitted once consistency of production is demonstrated or
16 justification is provided, with the agreement of the NRA.

17

18 **A.6.3 Control of diluents**

19 The general guidance provided in WHO good manufacturing practices for pharmaceutical
20 products: main principles (52) should be followed during the manufacture and quality control
21 of the diluents used to reconstitute the vaccine. An expiry date should be established for the
22 diluents based upon stability data. For lot release of the diluent, tests should be done to assess
23 its appearance, identity, volume and sterility, and the concentrations of its key components.

24 **A.7 Records**

25 The relevant guidance provided in WHO good manufacturing practices for pharmaceutical
26 products: main principles (52) and WHO good manufacturing practices for biological products
27 (53) should be followed as appropriate for the level of development of the vaccine.

28 **A.8 Retained samples**

29 The recommendations in section 9.5 of *WHO Good manufacturing practices for biological*
30 *products* (51) should be applied.

31 **A.9 Labelling**

32 The recommendations in section 7 of WHO Good manufacturing practices for biological
33 products (53) should be applied with the addition of the following:

34 The label on the carton or the leaflet accompanying the container should indicate:

- 1 – the streptococcal serotypes and carrier protein present in each single human
2 dose;
- 3 – the amount of each polysaccharide present in a single human dose for each GBS
4 serotype;
- 5 – the temperature recommended during storage and transport;
- 6 – if the vaccine is freeze-dried, that after its reconstitution it should be used
7 immediately unless data have been provided to the licensing authority showing
8 that it may be stored for a limited time;
- 9 – the volume and nature of the diluent to be added to reconstitute a freeze-dried
10 vaccine, specifying that the diluent should be supplied by the manufacturer and
11 approved by the NRA.

12 A.10 Distribution and transport

13 The guidance provided in WHO good manufacturing practices for pharmaceutical products:
14 main principles (52) and WHO good manufacturing practices for biological products (53)
15 should be followed.

16 Shipments should be maintained within specified temperature ranges, and packages
17 should contain cold-chain monitors. Further guidance on these and related issues is provided
18 in the WHO Model guidance for the storage and transport of time- and temperature-sensitive
19 pharmaceutical products (74).

20 A.11 Stability, storage and expiry date

21 The relevant guidance provided in WHO good manufacturing practices for biological products
22 (53) should be followed. Any statements concerning storage temperature and expiry date that
23 appear on primary or secondary packaging should be based on experimental evidence and
24 should be approved by the NRA.

25 A.11.1 Stability testing

26 Adequate stability studies are an essential part of the vaccine development studies. These
27 studies should follow the general principles outlined in *WHO Guidelines on stability evaluation
28 of vaccines (75)* and *WHO Guidelines on the stability evaluation of vaccines for use under
29 extended controlled temperature conditions (76)*. The shelf-life of the final product and the
30 hold time of each process intermediate (such as the purified polysaccharide, the carrier protein
31 and the purified bulk conjugate) should be established based on the results of real-time, real-
32 condition stability studies, and approved by the NRA.

33 The stability of the vaccine in its final container and at the recommended storage
34 temperature should be demonstrated to the satisfaction of the NRA on at least three lots of the
35 final product manufactured from different bulk conjugates. In addition, a real-time real-
36 condition stability study should be conducted on at least one final container lot produced each
37 year.

38 A protocol should be established and followed for each stability study which specifies
39 the stability-indicating parameters to be monitored, as well as the applicable specifications.

1 Some stability-indicating parameters may change over the shelf-life as discussed below. The
2 specifications should take into consideration the expected quality of the vaccine at the end of
3 shelf-life and should be linked to lots demonstrated to be safe and effective/immunogenic in
4 clinical trials. When a stability-indicating quality attribute changes over time, a tighter release
5 requirement may be applied to verify that the specification guaranteeing a safe and efficacious
6 product will be fulfilled.

7 The polysaccharide component of conjugate vaccines may be subject to gradual
8 hydrolysis at a rate that may vary with the type of conjugate, the type of formulation or
9 adjuvant, the type of excipients and conditions of storage. The hydrolysis may result in reduced
10 molecular size of the polysaccharide component, in a reduction in the amount of the
11 polysaccharide bound to the protein carrier and in a reduced molecular size of the conjugate
12 and increased levels of free polysaccharide.

13 Tests should be conducted before licensing to determine the extent to which the stability
14 of the product has been maintained throughout the proposed validity period. The vaccine
15 should meet the specifications for final product up to the expiry date.

16 If applicable, the residual moisture should be monitored as part of stability testing and
17 release testing.

18 Where applicable, the level of adsorption of the conjugate to the adjuvant should be
19 shown to be within the limits agreed with the NRA, unless data show that the immunogenicity
20 of the final product does not depend on the adsorption of the antigen to the adjuvant.

21 Accelerated stability studies may provide additional supporting evidence of the stability
22 of the product or other product characteristics, or both, but are not recommended for
23 establishing the shelf-life of the vaccine under a defined storage condition.

24 When any changes are made in the production process that may affect the stability of the
25 product, the vaccine produced by the new method should be shown to be stable.

26 The statements concerning storage temperature and expiry date appearing on the label
27 should be based on experimental evidence, which should be submitted for approval to the NRA.

28 **A.11.2 Storage conditions**

29 Storage conditions should be based on stability studies and approved by the NRA.

30 **A.11.3 Expiry date**

31 The expiry date should be approved by the NRA and based on the stability of the final product
32 as well as the results of the stability tests referred to in section A.9.1.

33 **Part B. Nonclinical evaluation of group B streptococcal conjugate vaccines**

34
35 This section addresses the pharmacological and toxicological testing of a candidate GBS
36 polysaccharide-protein conjugate vaccine. It provides guidance on the nonclinical evaluation
37 of vaccines intended to elicit antibody to GBS capsular polysaccharides in pregnant women in
38 order to protect their newborns against EOD and LOD. The guidance provided in this section
39 should be read in conjunction with the principles outlined in the WHO *guidelines on*

1 *nonclinical evaluation of vaccines* (12) and WHO *guidelines on the nonclinical evaluation of*
2 *vaccine adjuvants and adjuvanted vaccines* (13).

3 The need for, and the extent of, nonclinical evaluation in animals should be
4 scientifically justified on a product-specific basis. Where animal studies are undertaken, their
5 design and conduct should incorporate internationally accepted principles for the ethical use of
6 animals. The limitations of animal models in predicting human immune responses, protective
7 activity or safety should be acknowledged when interpreting nonclinical data (11-13).
8 Manufacturers are encouraged to consult the relevant NRA(s) at an early stage to agree on
9 appropriate nonclinical development strategies.

11 B.1 Primary pharmacodynamics

12
13 The ability of a GBS capsular-polysaccharide-protein conjugate vaccine to induce immune
14 responses should be carefully evaluated. For operational reasons, the manufacturer may
15 consider conducting the initial studies in non-pregnant adult female animals, using relevant
16 species that have been reported to develop anti-capsular antibody in response to GBS capsular
17 polysaccharide-protein conjugate vaccines, such as CD-1 mice, rats, or rabbits (59,77-80). In
18 general, the testing should include the clinically intended route of administration and dose
19 regimens, unless otherwise justified. The immune parameters to be evaluated should focus on
20 the binding and functional antibodies (e.g. opsonophagocytic) specific for GBS of homologous
21 capsular polysaccharides (CPS) present in the vaccine formulation as major outcomes, using
22 sera of the vaccinated animals. The immune responses to each CPS included in the final vaccine
23 formulation should be demonstrated. The studies may include exploration of dose-response by
24 testing of various dose levels of the vaccine, to help the selection of doses in early human trials.
25 For a vaccine candidate that contains adjuvant, the benefit of including it in the vaccine
26 formulation should be explored. Similarly, if a clinically intended dosing regimen includes two
27 vaccine doses to be given at a specific interval, the effect of the second dose administration on
28 vaccine immunogenicity should be investigated. It is expected that a promising vaccine
29 formulation will be able to raise strong and long-lasting antibody responses after the
30 completion of vaccination course.

31 However, it is important that the results of the initial studies in non-pregnant animals
32 are interpreted with caution if the serological assays used for the *in vitro* quantification of GBS
33 CPS-specific antibodies cannot distinguish the different types of antibodies, including IgG and
34 IgM. Both IgG and IgM antibodies could be raised by a GBS vaccine, whereas only the IgG
35 antibody is efficiently passed from mothers to their pups via the placenta. Therefore, the
36 nonclinical evaluation of vaccine immunogenicity using the blood of the pups born to the
37 vaccinated dams will provide most direct information. Such investigation may be carried out
38 within the context of developmental and reproductive toxicity (DART) studies, in which
39 immunogenicity should be assessed as part of DART, to provide evidence for passive antibody
40 transfer from dam to fetus and offspring. When such studies are pursued, consideration should
41 be given to the timing of vaccination in female animals. In such an animal model, too early
42 vaccination with a relatively weak immunogenic formulation may result in low IgG
43 concentrations in the newborn at birth. Accordingly, whether execution of animal vaccination

1 prior to mating, or to include an additional dose administered during early pregnancy to mount
2 the GBS CPS-specific IgG antibody response, should be considered on a case-by-case basis,
3 depending on the anticipated performance of the vaccine candidate from the initial studies
4 (81,82).

5 The data generated to characterize the immunogenicity of vaccine should be submitted
6 to support the further development in humans.

7 So far, there is no well-established immune correlate of protection against invasive GBS
8 in neonates and infants. A neonatal challenge model (77,78) was recently used to assess the
9 ability of vaccinated female mice to pass on maternal antibodies *in utero* which protect their
10 neonatal pups against a lethal challenge with virulent GBS. This model could be useful for
11 specific information on achieving newborn protection by a new GBS capsular polysaccharide-
12 protein conjugate vaccine after maternal immunization in animals, although acknowledging
13 that such data may not reliably predict the product performance in humans.

14 15 B.2 Pharmacokinetics

16
17 Studies to determine serum or tissue concentrations of vaccine components are normally not
18 needed. However, the understanding of distribution, quantity, and clearance of the administered
19 vaccine components following administration can be helpful in case of using novel excipients
20 or novel route of administration (e.g. oral, intranasal) (12,13).

21 22 B.3 Toxicology studies

23
24 Details on the design, conduct, analysis and evaluation of nonclinical toxicology studies are
25 available in *WHO guidelines for nonclinical evaluation of vaccines* (12) and *WHO guidelines*
26 *on the nonclinical evaluation of vaccine adjuvants and adjuvanted vaccines* (13). In addition,
27 international and regional documents on considerations for developmental toxicity studies for
28 preventative and therapeutic vaccines for infectious disease indications (81,82) may also be
29 informative. The aim of the study is to detect adverse effect, following exposure of the maternal
30 animal, on the pregnant females and development of the fetus as well as the offspring through
31 the weaning. The vaccination regimen should maximize maternal antibody titers and/or
32 immune response during the gestation period. Timing and number of doses will depend on the
33 onset and duration of the immune response to the vaccine. In general, and aligning with the
34 intended indication, maternal animal is dosed in later pregnancy. One or more additional doses
35 in the early gestation may be necessary to ensure the peak maternal antibody response and
36 consequently exposure of the fetus

37 Safety testing in animals is generally needed for the initiation of clinical studies in
38 humans, unless otherwise justified. DART data should be submitted to support the recruitment
39 of pregnant women in clinical trial (13, 81).

40 The vaccine lots used in pivotal toxicity studies should be adequately representative of
41 the formulation intended for clinical investigation and, ideally, should be the same lots used in
42 clinical studies. If this is not feasible, the lots used clinically should be comparable to those
43 used in the nonclinical studies in terms of potency, stability and other characteristics of quality.

1

2 **Part C. Clinical evaluation of group B streptococcal conjugate vaccines**

3 C.1 Introduction

4 Clinical trials with GBS polysaccharide-protein conjugate vaccines should be conducted in
5 accordance with the principles described in the *WHO Guidelines for good clinical practice*
6 *(GCP) for trials on pharmaceutical products* (83) and the *WHO Guidelines on clinical*
7 *evaluation of vaccines: regulatory expectations* (14).

8 This section addresses the clinical evaluation of GBS capsular polysaccharide-protein
9 conjugate vaccines intended for maternal immunization with the primary aim of preventing
10 invasive GBS disease in neonates and infants. The clinical programme that is outlined
11 addresses the possibility that the responsible NRA for any jurisdiction has agreed that initial
12 licensure may rest on safety and immunogenicity data. In particular, that the NRA has
13 concluded that vaccine-associated reduction in risk of invasive GBS disease may be inferred
14 from the proportions of cord blood samples that have anti-capsular IgG concentrations at or
15 above threshold values specific to serotypes and to EOD and LOD that have been derived from
16 sero-epidemiological studies. Therefore, this section is applicable only to GBS vaccines that
17 elicit anti-capsular antibody. While the clinical programme envisaged does not include conduct
18 of a pre-licensure vaccine efficacy trial, it anticipates that there are plans in place at time of
19 licensure for conduct of vaccine effectiveness studies.

20 The guidance assumes that control groups in clinical trials conducted in pregnant
21 women will be assigned to receive placebo. If a GBS vaccine has been licensed and withholding
22 this from the control groups is not considered possible in the jurisdiction(s) in which the trial(s)
23 will be conducted, the immune responses to the candidate vaccine should be assessed against
24 the pre-defined threshold values as discussed below. However, if there is a licensed GBS
25 capsular polysaccharide-protein conjugate vaccine for which vaccine effectiveness data are
26 available at least for EOD or LOD and/or for specific serotypes, the possibility of
27 immunobridging the candidate vaccine to the licensed vaccine for shared serotypes may be
28 considered and discussed with the responsible NRA(s).

29 Depending on the stage of development and available safety data, consideration could
30 be given to administering placebo to the control group followed by a licensed control vaccine
31 after a short delay (e.g. 2-4 weeks) while the test group receives the candidate vaccine followed
32 by placebo. In this way, placebo-controlled safety data can be generated for the candidate
33 vaccine should this be considered necessary.

34

35 C.2 Immunogenicity trials

36

37 C.2.1 Assays

38

39 General guidance on the use and validation of assays to determine immune responses to
40 vaccines is provided in the WHO Guideline on clinical evaluation of vaccines; regulatory

1 expectations (2). Whenever possible, results should be reported in International Unitage along
2 with information about the performance of any relevant International Standard(s).

4 ***C.2.1.1 Anti-capsular IgG***

5
6 The assay that is applied to sera obtained in clinical trials should be the same as or bridged to
7 the assay(s) used in the sero-epidemiological studies from which the threshold values to be
8 applied to cord blood anti-capsular IgG concentrations were derived. Adequate controls should
9 be used to define a valid test and justify pooling of data across assay runs.

11 ***C.2.1.2 Opsonophagocytic antibody (OPA)***

12
13 Due to the potential effect of antibacterial agents on the results of OPA assays, consideration
14 should be given to information on time between dosing and sample collection as well as
15 feasibility of inactivation of antibacterial agents in samples. The method used to calculate OPA
16 endpoint titres should be provided. Generally, it is recommended that the endpoint should be
17 derived from the linear portion of the titration curve.

19 **C.2.2 Trial population and design**

21 ***C.2.2.1 Nonpregnant women of childbearing age***

22
23 The first clinical trials are expected to provide data on safety and immunogenicity in
24 nonpregnant female participants of childbearing age who are randomised to receive candidate
25 vaccine formulations or placebo. It is highly desirable and generally expected that a single dose
26 of a candidate polysaccharide-protein conjugate vaccine will suffice such that a second dose
27 does not elicit a potentially clinically important increment in antibody levels.

28 The immunogenicity data obtained in non-pregnant women of childbearing age should
29 be used to select the vaccine formulation(s) to be tested in pregnant women. Before progressing
30 to trials in pregnant female participants, the safety data obtained from non-pregnant female
31 participants should be considered sufficient to rule out any major concerns for use during
32 pregnancy, such as risk for high fever in the first days after vaccination.

34 ***C.2.2.2 Pregnant women***

35
36 The minimum and maximum periods of gestation for enrolment into trials in pregnant women
37 should cover the intended range for use. It is generally recommended that the duration of
38 pregnancy at time of enrolment is determined from an ultrasound examination that was
39 conducted before or at around week 18 of gestation. Reflecting the peak period of placental
40 transfer of IgG, and assuming that only one dose of vaccine is required, it is recommended that
41 participants should have completed at least 24 weeks and no more than 36 weeks of gestation
42 when vaccinated. Consideration should be given to enrolling adequate cohorts at weeks 24-28,

1 28-32 and 32-36 weeks of gestation when vaccinated to provide insight into any effect there
2 may of gestational stage to maternal immune response and to cord blood antibody levels.

3
4 Furthermore, at least in initial trials in pregnant women, sponsors may wish to limit enrolment
5 to singleton pregnancies with no known fetal abnormalities and no evidence of placental
6 insufficiency. If women who test positive for HIV are to be excluded from the first clinical
7 trial(s), consideration should be given to generating sufficient immunogenicity data in HIV-
8 positive women so that they may be included in Phase 3 trials with or without stratification at
9 randomisation by HIV status.

10 11 *C.2.2.2.1 Dose-finding trials*

12
13 The final vaccine formulation and dose for Phase 3 trials in pregnant women should be selected
14 from the infant cord blood data obtained in the dose-finding trial(s). The final candidate vaccine
15 should maximize the proportions of neonates born to vaccinated mothers who have cord blood
16 anti-capsular IgG concentrations above the selected serotype-specific threshold values for EOD
17 and/or LOD whilst maintaining an acceptable safety profile. Additionally, the final candidate
18 vaccine should maximize the difference in cord blood anti-capsular IgG concentrations
19 between infants born to vaccinated and unvaccinated mothers. Dose-finding trials in pregnant
20 women should include determination of maternal anti-capsular IgG at approximately 4 weeks
21 post-vaccination with additional samples collected at least from a subset to describe antibody
22 kinetics. Consideration should be given to investigating the safety and immunogenicity of
23 revaccination during a subsequent pregnancy whenever the opportunity arises in the post-
24 approval period.

25 26 *C.2.2.2.2 Phase 3 trials*

27
28 Phase 3 trials may be conducted in individual NRA jurisdictions and/or in several countries
29 and geographical regions. As applicable, the data may provide a broad assessment of immune
30 responses and capture regional predominant serotypes. Consideration may also be given to
31 stratification of enrolment by country and/or region.

32 The primary immunological readout in Phase 3 trials should be the cord blood anti-
33 capsular IgG concentrations with calculation of proportions of neonates with levels for each of
34 EOD and LOD above the threshold values for each serotype included in the vaccine.

35 The proportions of neonates born to each of vaccinated or unvaccinated mothers who
36 have cord blood IgG concentrations above the selected threshold values for EOD and LOD and
37 for individual vaccine serotypes should be calculated. The final licensing decision must be
38 based on the totality of the data and the anticipated overall protection against invasive GBS
39 disease that might be anticipated in the individual NRA's jurisdiction.

40 It is suggested that sponsors and NRAs should pre-agree the desirable precision around
41 the proportions with cord blood IgG above the threshold values across vaccine serotypes for
42 EOD and LOD. The sample size calculation should also ensure that the total mother-infant
43 pairs exposed to the final candidate vaccine provides an adequate safety database.

1 Additional immunological readouts should include the OPA titres in cord blood and
2 the maternal anti-capsular IgG levels for each serotype in the vaccine at 4 weeks after
3 vaccination. Depending on prior data accrued, it may be sufficient to obtain these data from a
4 randomly selected subset of samples. Follow-up samples should be obtained, as described in
5 dose-finding trials.

6 As applicable to each immunological readout, descriptive analyses should include the
7 seroconversion rates, geometric means and geometric mean fold increases. Also, cord blood
8 anti-capsular IgG levels may be explored by gestation elapsed at time of maternal vaccination
9 and by time elapsed between maternal vaccination and delivery.

10 Depending on the carrier protein in the GBS polysaccharide-protein conjugate vaccine,
11 the infant immune responses to relevant routine infant vaccines should be determined at least
12 for a subset during dose-finding and/or Phase 3 trials. For example, if the carrier protein is
13 CRM197, infant immune responses to diphtheria toxoid and to any conjugate vaccine that has
14 CRM197 as the carrier protein should be determined.

15 Infants born to vaccinated mothers should be followed for post-natal development up
16 to the age of approximately 6 months. Consideration should be given to following randomised
17 subsets of infants enrolled in Phase 3 trials post-licensure to assess longer-term postnatal
18 development.

20 C.3 Efficacy trials

21
22 As discussed under *General considerations*, it will be for the individual NRA to determine the
23 acceptability of initial licensure based on safety and immunogenicity data after considering the
24 reliability and relevance of published threshold values of cord blood anti-capsular Ig antibody
25 that appear to correlate with reduction in risk of invasive GBS disease.

26 If initial licensure based on the application of threshold anti-capsular antibody levels is
27 not considered acceptable for any reason, NRAs and sponsors are referred to the WHO
28 Guideline on clinical evaluation of vaccines; regulatory expectations (14), which provides
29 guidance on the design of efficacy trials.

31 C.4 Vaccine effectiveness studies

32
33 It is essential that there are plans in place at time of initial licensure to estimate vaccine
34 effectiveness. The aim of these studies should include estimating vaccine effectiveness against
35 invasive GBS due to any vaccine serotype and, depending on what may be supported by the
36 data collected, by serotype and by EOD and LOD. Consideration should be given to conducting
37 effectiveness studies in different regions according to the use of IAP. Furthermore, whenever
38 possible, these studies should include collection of cord blood samples and determination of
39 anti-capsular IgG to support or revise the threshold values that may predict protection against
40 invasive GBS. Potentially, at least subsets of these samples could be used to determine OPA
41 titres to attempt to further evaluate correlations with protection against invasive GBS.

42 It is anticipated that certain countries will include a GBS capsular polysaccharide-
43 protein conjugate vaccine in routine antenatal care shortly after initial licensure along with

1 national programmes designed to collect data that may support estimates of vaccine
2 effectiveness by serotype and for EOD and LOD. While the license holders will likely not be
3 involved in such programmes, they should be aware of the timelines for reporting the results
4 and should include such studies in the list of post-licensing activities. Moreover, there may be
5 some jurisdictions in which the responsible NRAs request that the license holder conducts a
6 vaccine effectiveness study in co-operation with the public health authorities or, at least,
7 undertakes the determination of cord blood anti-capsular IgG concentrations. Each NRA
8 should receive a comprehensive list of all such studies, each stating the role (if any) of the
9 license holder, which should be updated at regular intervals.

11 **C.4.1 Study design**

12
13 There are several possible designs that may be considered, as discussed in the WHO Guideline
14 on clinical evaluation of vaccines: regulatory expectations (14).

15 The population to be vaccinated will reflect the prescribing information and the
16 decisions made by the relevant public health authority on any exclusions to be made from the
17 target population.

18 To support the estimates of vaccine effectiveness, there should be high confidence in
19 the completeness of disease surveillance along with guidance on the samples to be obtained
20 from all suspected cases of invasive GBS disease. The method of case ascertainment should be
21 tailored to the healthcare system but should be as comprehensive as possible, including
22 instructions to pregnant women, infant care-givers and relevant healthcare professionals,
23 especially midwives, obstetricians and paediatricians, on trigger signs and symptoms for
24 possible invasive GBS disease. The primary case definitions for GBS EOD and LOD should
25 require both clinical and laboratory criteria to be met. Laboratories should be competent to
26 process samples and arrange shipping to designated centres for determination of serotypes.

28 **C.4.2 Study analysis**

29
30 It is recommended that vaccine effectiveness studies should be designed primarily to estimate
31 the reduction in risk for invasive GBS disease due to any vaccine serotype and, assuming
32 enough cases are accrued, to also estimate this by serotype for EOD and for LOD separately.
33 The data may also be explored according to timing of vaccination during gestation and time
34 elapsed between vaccination and delivery.

35 Vaccine effectiveness studies also present the possibility to explore any potential
36 benefit of GBS capsular polysaccharide-protein conjugate vaccines on maternal complications
37 in later pregnancy or in the peri-partum period as well as rates of pre-term birth or stillbirth. If
38 these endpoints are incorporated into vaccine effectiveness studies, there must be adequate case
39 definitions supported by clinical and laboratory criteria.

40 In countries that already had comprehensive surveillance for invasive GBS disease in
41 place prior to introducing vaccination, assuming that the annual incidence of disease was
42 documented to be generally stable, there is the potential to compare rates of invasive GBS
43 disease before and after implementing routine vaccination as well as examining the proportions

1 of cases due to individual serotypes and any differential effects there may have been on EOD
2 vs. LOD. If the policy on use of IAP is modified at any time after introduction of routine
3 vaccination in a specific country or region, a vaccine effectiveness study may also be used to
4 examine any change in incidence of EOD that may occur.

5 C.5 Safety aspects

6 Candidate GBS polysaccharide-protein conjugate vaccines must have acceptable safety
7 profiles in pregnant women. The risk of local and systemic reactions to vaccination, including
8 fever, should be assessed in non-pregnant women before proceeding to vaccinate pregnant
9 women. The data should not suggest any undue concerns for use during the second and third
10 trimesters. For example, the rates of fever, especially high fever, should be low to negligible.

11 The rates of premature delivery, complications of pregnancy or labour and the condition
12 of infants at birth should be compared between the vaccinated and unvaccinated groups.

13 It is recommended that serious adverse events should be documented for 6 months after
14 maternal vaccination and for 6 months post-natal in their infants.

15

16 Part D. Guidelines for NRAs

17

18 D.1 General

19

20 The guidance for NRAs and national control laboratories (NCLs) given in the *WHO Guidelines*
21 *for national authorities on quality assurance for biological products* (84) and *WHO Guidelines*
22 *for independent lot release of vaccines by regulatory authorities* (85) should be followed.
23 These guidelines specify that no new biological product should be released until consistency
24 of lot manufacturing and quality has been established and demonstrated by the manufacturer.

25 The detailed production and control procedures, as well as any significant changes in
26 them that may affect the quality, safety or efficacy of the conjugate vaccine, should be
27 discussed with and approved by the NRA.

28 For control purposes, the relevant international reference preparations currently in force
29 should be obtained for the purpose of calibrating national, regional and working standards as
30 appropriate. The NRA may obtain from the manufacturer the product-specific or working
31 reference to be used for lot release.

32 Consistency of production has been recognized as an essential component in the quality
33 assurance of vaccines. The NRA should carefully monitor production records and quality
34 control test results for clinical lots, as well as for a series of consecutive lots of the monovalent
35 bulk conjugates as well as for the final bulk or final product.

36

37 D.2 Official release and certification

38

39 A vaccine lot should be released only if it fulfils all national requirements and/or satisfies Part
40 A of these WHO Recommendations (85).

1 A summary protocol for the manufacturing and control of GBS conjugate vaccines,
2 based on the model summary protocol provided below in Appendix 1 and signed by the
3 responsible official of the manufacturing establishment, should be prepared and submitted to
4 the NRA/NCL in support of a request for the release of a vaccine for use. This protocol may
5 also be referred to as the Product Specification File.

6 A lot release certificate signed by the appropriate NRA/NCL official should then be
7 provided if requested by the manufacturing establishment, and should certify that the lot of
8 vaccine meets all national requirements and/or Part A of these WHO Recommendations. The
9 certificate should provide sufficient information on the vaccine lot, including the basis of the
10 release decision (by summary protocol review or independent laboratory testing). The purpose
11 of this official national lot release certificate is to facilitate the exchange of vaccines between
12 countries and should be provided to importers of the vaccines.

13 A model NRA/NCL Lot Release Certificate for GBS conjugate vaccines is provided
14 below in Appendix 2.

16 **Authors and acknowledgements**

17
18 The first draft was prepared by a drafting group comprising: Dr I. Feavers (consultant, UK);
19 Dr Y. Sun (Paul-Ehrlich-Institut, Germany); Dr M. Powell (consultant, UK); and Dr T.Q.
20 Zhou (WHO, Switzerland). The resulting document was posted on the WHO Biologicals
21 website for a first round of public consultation from 10 December 2025 to 30 January 2026.
22 Comments were received from: Dr A. Buoninfante, European Medicines Agency, the
23 Netherlands; Dr R. Burki, Biological E. Limited, India; Dr P. Barbosa, International
24 Federation of Pharmaceutical Manufacturers and Associations (IFPMA), Switzerland; Dr G.
25 Enwere, Nigeria; Prof. D. Goldblatt, University College London, United Kingdom; Dr E.
26 Griffiths, United Kingdom; Dr M. Gruber, International Alliance for Biological
27 Standardization (IABS); Dr R. Isbrucker; Dr T. Wu and Dr R. Siggers, Health Canada,
28 Canada; Dr J. Liu, Suzhou Juwei Biotech Co., Ltd, People's Republic of China; Dr A.
29 Lignell, Dr F. Jalalvand, Dr C. Bergquist, Dr F. Josephson, and Dr M. Welin, Swedish
30 Medical Products Agency, Sweden; Dr M. Xu, National Institutes for Food and Drug
31 Control, People's Republic of China; Dr L. Wijnans, Dr I. Schellens, Dr R. Donken, Dr C. de
32 Wolf, and Dr G. Tiesjema, Medicines Evaluation Board, the Netherlands; Dr A. Seale, Gates
33 Foundation, United Kingdom; Dr M-C. Uwamwezi, PATH, Belgium; and Dr C. Whitney,
34 Child Health and Mortality Prevention Surveillance (CHAMPS), The Task Force for Global
35 Health, United States of America.

36 The current second draft was then prepared by the same drafting group taking into
37 consideration the comments received from the first round of public consultation.

Appendix 1

Model summary protocol for the manufacturing and control of group B streptococcal conjugate vaccines

The following protocol is intended for guidance. It indicates the information that should be provided as a minimum by the manufacturer to the NRA or NCL.

Information and tests may be added or omitted as necessary with the approval of the NRA or NCL. In cases where the testing method is different from the one listed in this model protocol, it should be approved by the NRA.

It is possible that a protocol for a specific product may differ in detail from the model provided here. The essential point is that all relevant details demonstrating compliance with the licence and with the relevant WHO recommendations for a particular product should be provided in the protocol submitted.

The section concerning the final product should be accompanied by a sample of the label and a copy of the leaflet (package insert) that accompanies the vaccine container. If the protocol is being submitted in support of a request to permit importation, it should also be accompanied by a lot release certificate (see Appendix 2) from the NRA or NCL of the country in which the vaccine was produced and/or released, stating that the product meets all national requirements as well as Part A of these WHO Guidelines.

1. Summary information on final lot

International name of product: _____

Commercial name: _____

Product licence (marketing authorization) number: _____

Country: _____

Name and address of manufacturer: _____

Nature of final product: _____

Final packaging lot number: _____

Type of container: _____

Final container lot number: _____

Number of containers in this final lot: _____

Number of doses per final container: _____

Volume of each recommended single human dose: _____

Preservative used and nominal concentration: _____

Summary of composition (*include a summary of the qualitative and quantitative composition of the vaccine per single human dose; including the conjugate, any adjuvant used and other excipients*):

1
 2 Shelf-life approved (months): _____
 3 Date of manufacture: _____
 4 Expiry date: _____
 5 Storage conditions: _____

6 7 **2. Detailed information on manufacture and control**

8
 9 *The following sections are intended for reporting the results of the tests performed during the*
 10 *production of the vaccine, so that the complete document will provide evidence of consistency*
 11 *of production. If any test had to be repeated, this information must be indicated. Any abnormal*
 12 *results must be recorded on a separate sheet.*

13 14 **Summary of source materials**

15
 16 It is possible that a number of bulk lots may be used to produce a single final lot. A summary
 17 of the bulk polysaccharide, activated saccharide, bulk carrier protein and bulk conjugate lots
 18 that contributed to the final lot should be provided.

19 20 **Control of serotype-specific GBS polysaccharides**

21 22 **Bacterial strain**

23 Identity of bacterial strains used (i.e. for each serotype): _____
 24 Origin and short history: _____
 25 Authority that approved the strain: _____
 26 Date approved: _____

27 28 **Bacterial culture media for seed-lot preparation and polysaccharide production**

29 Free from ingredients that form precipitate when CTAB is added: _____
 30 Free from toxic or allergenic substances: _____
 31 Any components of animal origin (list): _____
 32 Certified as TSE-free: _____

33 34 **Master seed lot**

35 Lot number: _____
 36 Date master seed lot established: _____

37 38 **Working seed lot**

39 Lot number: _____

1 Date working seed lot established: _____

2 Type of control tests used on working seed lot: _____

3 Date seed lot reconstituted: _____

4

5 **Control of single harvests**

6 *For each single harvest, indicate the medium used; the dates of inoculation; the temperature*
7 *of incubation; the dates of harvests and harvest volumes; the results of tests for bacterial*
8 *growth rate, pH, purity and identity; the method and date of inactivation if used; the method*
9 *of purification; and the yield of purified polysaccharide.*

10

11 **Control of purified GBS polysaccharides**

12 Lot number: _____

13 Date of manufacture: _____

14 Volume: _____

15

16 ***Identity***

17 Date tested: _____

18 Method used: _____

19 Specification: _____

20 Result: _____

21

22 ***Polysaccharide content***

23 Date tested: _____

24 Method used: _____

25 Specification: _____

26 Result: _____

27

28

29 ***Molecular size or mass distribution***

30 Date tested: _____

33 Result: _____

34

35 ***Moisture content***

36 Date tested: _____

1 Method used: _____

2 Specification: _____

3 Result: _____

4

5 ***Protein impurity***

6 Date tested: _____

7 Method used: _____

8 Specification: _____

9 Result: _____

10

11 ***Nucleic acid impurity***

12 Date tested: _____

13 Method used: _____

14 Specification: _____

15 Result: _____

16

17 ***Pyrogen content***

18 Date tested: _____

19 Method used: _____

20 Specification: _____

21 Result: _____

22

23 ***Residues of process-related contaminants***

24 Date tested: _____

25 Method used: _____

26 Specification: _____

27 Result: _____

28

29 **Control of modified polysaccharide**

30 Lot number: _____

31 Method of chemical modification: _____

32

33 ***Extent of activation for conjugation***

34 Date tested: _____

35 Method used: _____

1 Specification: _____

2 Result: _____

3

4 ***Molecular size or mass distribution***

5 Date tested: _____

6 Method used: _____

7 Specification: _____

8 Result: _____

9

10 **Control of carrier protein**

11

12 **Microorganisms used**

13 Identity of strain used to produce carrier protein: _____

14 Origin and short history: _____

15 Authority that approved the strain: _____

16 Date approved: _____

17

18 **Bacterial culture media for seed-lot preparation and carrier-protein production**

19 Free from ingredients that form precipitate when CTAB is added: _____

20 Free from toxic or allergenic substances: _____

21 Any components of animal origin (list): _____

22 Certified as TSE free: _____

23

24 **Master-seed lot**

25 Lot number: _____

26 Date master-seed lot established: _____

27

28 **Working-seed lot**

29 Lot number: _____

30 Date established: _____

31 Type of control tests used on working-seed lot: _____

32 Date seed lot reconstituted: _____

33

34 **Control of carrier-protein production**

35 *List the lot numbers of harvests: indicate the medium used; the dates of inoculation; the*
36 *temperature of incubation; the dates of harvests and harvest volumes; the results of tests for*

1 *bacterial growth rate, pH, purity and identity; the method and date of inactivation; the method*
2 *of purification; and the yield of purified carrier protein. Provide evidence that the carrier*
3 *protein is nontoxic.*

4
5 **Purified carrier protein**

6 Lot number: _____

7 Date produced: _____

8
9 ***Identity***

10 Date tested: _____

11 Method used: _____

3. Certification by the manufacturer

Name of head of production and/or quality control (typed) _____

Certification by the person from the control laboratory of the manufacturing company taking overall responsibility for the production and quality control of the vaccine.

I certify that lot no. _____ of multivalent GBS conjugate vaccine, whose number appears on the label of the final containers, meets all national requirements and satisfies Part A⁵ of the WHO Guidelines to assure the quality, safety and efficacy of GBS conjugate vaccines.⁶

Signature _____

Name (typed) _____

Date _____

4. Certification by the NRA/NCL

If the vaccine is to be exported, attach the model NRA/NCL Lot Release Certificate for GBS conjugate vaccines (as shown in Appendix 2), a label from a final container and an instruction leaflet for users.

⁵ With the exception of provisions on distribution and transport, which the NRA may not be in a position to assess.

⁶ WHO Technical Report Series, No. XXXX, Annex X.

1 **Appendix 2**

2
3 **Model NRA/NCL Lot Release Certificate for group B streptococcal**
4 **conjugate vaccines**

5
6
7 This certificate is to be provided by the NRA or NCL of the country in which the vaccine has
8 been manufactured, on request by the manufacturer.

9
10
11
12 Certificate no. _____

13
14
15
16 The following lot(s) of GBS conjugate vaccine produced by

17 _____⁷
18 in _____,⁸ whose numbers
19 appear on the labels of the final containers, meet all national requirements⁹ and Part A¹⁰ of the
20 WHO Guidelines to assure the quality, safety and efficacy of group B streptococcal conjugate
21 vaccines,¹¹ and comply with WHO good manufacturing practices for pharmaceutical products:
22 main principles;¹² WHO good manufacturing practices for biological products;¹³ and the WHO
23 Guidelines for independent lot release of vaccines by regulatory authorities.¹⁴

24
25
26 The release decision is based on _____¹⁵

27
28
29 Final lot number _____

30 Number of human doses released in this final lot _____

31 Expiry date _____

32
33

⁷ Name of manufacturer.

⁸ Country of origin.

⁹ If any national requirements have not been met, specify which one(s) and indicate why the release of the lot(s) has nevertheless been authorized by the NRA or NCL.

¹⁰ With the exception of provisions on distribution and transport, which the NRA or NCL may not be in a position to assess.

¹¹ WHO Technical Report Series, No. XXXX, Annex X.

¹² WHO Technical Report Series, No. 986, Annex 2.

¹³ WHO Technical Report Series, No. 999, Annex 2.

¹⁴ WHO Technical Report Series, No. 978, Annex 2.

¹⁵ Evaluation of the product-specific summary protocol, independent laboratory testing and/or specific procedures laid down in a defined document, and so on as appropriate.

1 The certificate may also include the following information:
2

- 3 ▪ name and address of manufacturer;
- 4 ▪ site(s) of manufacturing;
- 5 ▪ trade name and/or common name of product;
- 6 ▪ marketing authorization number;
- 7 ▪ lot number(s) (including sub-lot numbers and packaging lot numbers if necessary);
- 8 ▪ type of container;
- 9 ▪ number of doses per container;
- 10 ▪ number of containers or lot size;
- 11 ▪ date of start of period of validity (for example, manufacturing date);
- 12 ▪ storage conditions;
- 13 ▪ signature and function of the person authorized to issue the certificate;
- 14 ▪ date of issue of certificate.

15

16
