

A.52	Zanubrutinib – chronic lymphocytic leukaemia/small lymphocytic lymphoma – EML
Draft recommendation	<p><input type="checkbox"/> Recommended</p> <p><input checked="" type="checkbox"/> Not recommended</p> <p>Justification:</p> <p>I do not support the inclusion of zanubrutinib on the EML for treatment of chronic lymphocytic leukaemia/small lymphocytic lymphoma at this time.</p> <p>Progression-free survival is significantly improved in patients treated with zanubrutinib versus bendamustine and rituximab (BR) (HR 0.42) but not overall survival. Of note, deaths are numerically higher in the zanubrutinib arm, and high rate of hemorrhage and secondary primary malignancies (21%) is concerning. The BR control arm is suboptimal and should have been rather than time limited BR. In conclusion, in my opinion, the lack of survival advantage and the safety signal suggest that more data and longer follow up are needed before making a recommendation.</p> <p>It was noted that while data supported progression-free survival gains from zanubrutinib when compared to ibrutinib, another TKI recommended by WHO as an essential medicine, the magnitude of these gains may be limited, and that few long-term and real-world data were available. Furthermore, high rates of toxicity (particularly neutropenia) and limited information on prices with uncertain cost-effectiveness (given lower doses that can be used with ibrutinib as compared to those proposed in the application) are acknowledged as limitations for the procurement and use of zanubrutinib.</p>
Does the proposed medicine address a relevant public health need?	<p><input checked="" type="checkbox"/> Yes</p> <p><input type="checkbox"/> No</p> <p><input type="checkbox"/> Not applicable</p> <p>Comments:</p> <p>Chronic lymphocytic leukaemia is the most common form of leukaemia in western countries. Globally, the number of deaths due to chronic lymphocytic leukaemia has increased in 70% from 1990 to 2017. However, the age-adjusted death rates have decreased in high-income regions while increased in Central Sub-Saharan Africa, East Asia, and Southeast Asia.</p> <p>While being mostly regarded as an indolent disease, it nonetheless has a wide range of clinical manifestations and is a life-limiting condition. All individuals with CLL/SLL who require therapy will eventually relapse since the illness is still incurable. There is a wide range in the prognosis for various CLL/SLL patients, with the median overall survival (OS) being around 10 years. While 20% of patients present with a very aggressive appearance and have a median OS of 1.5–3 years, other people can live for years.</p>
