Human infection with avian influenza A(H5) viruses

Human infection with avian influenza A(H5N1) virus
Between 19 May and 25 May 2023, no new cases of human infection with avian influenza A(H5N1) virus were reported to WHO in the Western Pacific Region.

As of 24 April 2023, a total of 244 cases of human infection with avian influenza A(H5N1) virus have been reported from four countries within the Western Pacific Region since January 2003 (Table 1). Of these cases, 136 were fatal, resulting in a case fatality rate (CFR) of 56%. The most recent cases in the WPR were reported from Cambodia on 23 and 24 February 2023, in an 11-year-old girl who died and her father who survived.

Table 1: Cumulative number of laboratory-confirmed human cases (C) and deaths (D) of influenza A(H5N1) virus infection reported to WHO, by date of onset (January 2003 to 24 April 2023), Western Pacific Region

NB: This table is updated on a monthly basis following the updates from the Source

Globally, from January 2003 to 24 April 2023, 874 cases of human infection with avian influenza A(H5N1) virus were reported from 23 countries. Of these 874 cases, 458 were fatal (CFR of 52%) (Source).

Human infection with avian influenza A(H5N6) virus
Between 19 May and 25 May 2023, no new cases of human infection with avian influenza A(H5N6) virus were notified to WHO in the Western Pacific Region.

To date, a total of 84 laboratory-confirmed cases of human infection with influenza A(H5N6) virus including 33 deaths have been reported to WHO in the Western Pacific Region since 2014.

The last case was reported from China, with an onset date of 17 December 2022. The case was hospitalized on 21 December 2022 with severe pneumonia and has since recovered.

Human infection with avian influenza A(H5) virus
Between 19 May and 25 May 2023, no new cases of human infection with avian influenza A(H5) virus were notified to WHO in the Western Pacific Region. The last case was reported from Vietnam, with an onset date of 22 October 2022 (one case, no death). This is the first case of avian influenza A(H5) reported from Vietnam since 2014; NA subtype could not be determined.
Public health risk assessment for human infection with avian influenza A(H5) viruses

Whenever avian influenza viruses are circulating in poultry, there is a risk for sporadic infection and small clusters of human cases due to exposure to infected poultry or contaminated environments. Therefore, sporadic human cases are not unexpected.

The rise in the number of reported human cases of A(H5N6) infection may reflect the continued circulation of the virus in birds, and enhanced surveillance system and diagnostic capacity as a direct outcome of the response to the COVID-19 pandemic. The zoonotic threat remains elevated due to the spread of the viruses among birds. However, the overall pandemic risk associated with A(H5) is considered not significantly changed in comparison to previous years. WHO recommends that Member States remain vigilant and consider mitigation steps to reduce human exposure to potentially infected birds to reduce the risk of additional zoonotic infection.

For information on risk assessments on Avian Influenza, see: monthly risk assessment summaries and Assessment of risk associated with highly pathogenic avian influenza A(H5N6) virus.

Human infection with avian influenza A(H3N8) virus

Between 19 May and 25 May 2023, no cases of human infection with avian influenza A(H3N8) virus were reported to WHO in the Western Pacific Region.

To date, a total of 3 laboratory-confirmed cases of human infection with influenza A(H3N8) virus with one death have been reported to WHO in the Western Pacific Region.

Human infection with avian influenza A(H7N4) virus in China

Between 19 May and 25 May 2023, no new cases of human infection with avian influenza A(H7N4) virus were reported to WHO in the Western Pacific Region. To date, only one laboratory-confirmed case of human infection with influenza A(H7N4) virus has been reported to WHO. This case was reported from China on 14 February 2018.

Human infection with avian influenza A(H7N9) virus in China

Between 19 May and 25 May 2023, no new cases of human infection with avian influenza A(H7N9) virus were reported to WHO in the Western Pacific Region. To date, a total of 1,568 laboratory-confirmed human infections with avian influenza A(H7N9) virus, including 616 fatal cases (CFR: 39%), have been reported to WHO since early 2013. The last case of human infection with avian influenza A(H7N9) reported to WHO in the Western Pacific Region was in 2019.

Of the 1,568 human infections with avian influenza A(H7N9), 33 have reported mutations in the hemagglutinin gene indicating a change to high pathogenicity in poultry. These 33 cases were from Taiwan, China (one case had a travel history to Guangdong), Guangxi, Guangdong, Hunan, Shaanxi, Hebei, Henan, Fujian, Yunnan, and Inner Mongolia. No increased transmissibility or virulence of the virus within human cases related to the HPAI A(H7N9) virus has been detected.

WHO is continuing to assess the epidemiological situation and will conduct further risk assessments as new information becomes available. The number and geographical distribution of human infections with avian influenza A(H7N9) viruses in the fifth epidemic wave (1 October 2016 to 30 September 2017) were greater than previous waves and the subsequent waves.
Further sporadic human cases of avian influenza A(H7N9) virus infection are expected in affected and possibly neighbouring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. However, if this were to occur, the community-level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

To date, there is no evidence of sustained human-to-human transmission of avian influenza A(H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and transmission behavior to humans as this may have serious public health impacts.

**Human infection with avian influenza A(H9N2) virus**

Between 19 May and 25 May 2023, no new cases of human infection with avian influenza A(H9N2) were reported to WHO in the Western Pacific Region.

To date, a total of 87 cases of human infection with avian influenza A(H9N2), including two deaths (both with underlying conditions have been reported to WHO in the Western Pacific Region since December 2015. Of these, 85 were reported from China and two were reported from Cambodia. The last case was reported from China, with an onset date of 5 February 2023, and has since recovered.

**Human infection with avian influenza A(H10N3) virus**

Between 19 May and 25 May 2023, no new cases of human infection with avian influenza A(H10N3) virus were reported to WHO in the Western Pacific Region. To date, two cases of avian influenza A(H10N3) virus have been reported globally.

The last case was reported from Zhejiang - China with an onset date of 11 June 2022 and has since recovered.

Most previously reported human infections with avian influenza viruses were due to exposure to infected poultry or contaminated environments. Since avian influenza viruses, including avian influenza A(H10N3) viruses, continue to be detected in poultry populations, further sporadic human cases could be detected in the future. Currently, available epidemiologic information suggests that the avian influenza A(H10N3) virus has not acquired the ability for sustained human-to-human transmission, thus the likelihood of spread among humans is low.

**Animal infection with avian influenza virus**

Between 19 May and 25 May 2023, no new outbreaks of high pathogenicity avian influenza among birds were notified to the World Organization for Animal Health (WOAH) from the Western Pacific Region.
